Again though, remember that once the lengh of the wire is greater than 1/2 wavelengh the pattern starts to form lobes that can give you a great signal - somewhere - and an equally poor signal in other places. This is true for a windom too, on its harmonic bands. That is why 40 meter windoms exist (besides the fact that they are shorter).

One of the best ways to solve your problem is by reading. Fortunately these days you can read about antennas for hours on the internet at no cost, but the best books I've found over the years are the ARRL Anthology series and of course the ARRL antenna book.

Nice and very useful, but appears to not do log scales as I believe
the OP wants. I hacked a simple Excel spreadsheet that would do fine,
except for the fact that Excel plots INCORRECT size segments
sometimes! Grrrr. Otherwise seems like it would be fine; it prints
just fine, to whatever your printer resolution is.

If the OP wants to try it in Excel perhaps a different way than he
first tried, here's what I did...
o One cell for degrees span, referenced in
next-to-last step.
o Make a column with the values where you want tics
(e.g., 1, 2, 4, 6, 8, 10, 20, 40, 60, 80, 100).
There can be any number of them, at any values
(in sequence, of course).
o Next column over, take the log of the tic values
o Next column over, take the differences between
adjacent values in previous (log) column.
There will be n-1 of them.
o Just below last cell of differences column, create
a cell with
sum(column_above)*(360-degrees_span)/degrees_span
in it.
o Create a "donut" plot of the n values in the last
column. Adjust the colors to be all the same (or
not, as you please) and the inner circle to be
the radius you want. This doesn't label the tics,
but you should be able to do that in other progs
if you want. And the tics are all the same
length, which is suboptimal.

Should be easy to do in Scilab, too, and use Ghostscript to print
(like Panel and Dial do). That gives the ability to make different
size tics and to label them.

Cheers,
Tom

Hey! Another swell use for Excel. I just did my meter faces with a drawing program. I do all kinds of graphing in Excel.

I really don't think it matters if it's a democrat or republican in the
White House... Powell it just a political appointee who really has no clue
as to how radio works. Doesn't matter if the head of the FCC was appointed
by a democrat or republican president... whoever they appoint is most likely
totally ignorant of the department they head. They are all politicians and
bureaucrats first, and knowlegable about radio second. He will do whatever
helps him, not what benefits HF radio. However, he has no idea what kind of
quagmire he is going to get into when BPL causes such massive interference
that the FCC will surely have to put an end to it.

<off topic>
I disagree emphatically.

I got a ham license precisely *because* of Powell and the nbeocon
corruption/coercion of the mass media communications channels. I was
impressed that the regulations (so far) allow political discussions
over the airwaves.

Bush may personally not understand facts-and-data, but I don't think
his appointees can skate by with that excuse. Powell is corrupt, not
dumb.

In the olden days (say Goldwater's era) we had Democrats and
Republicans with honorable intentions but a difference of opinion on
how to do things. But these days, the neocons are just corporations
hijacking our country. Media consolidation, IRAQ for the oil, stall

on global warming, PATRIOT Act as corporate-managed KGB, bankrupt the nation so regulators and auditors cannot do their jobs, etc.

</off topic>

1412. Re: Designing Frequency-Dependent Impedances?

Diego: if you want to make an impedance out of regular parts, I'm afraid you don't have too much to work with. Impedances made of R, L , and C's have certain rerqirements: for example, the numberof poles and zeros cannot differ by more than 1.

If you can use active parts, though, you can get all sorts of impedances. You have to be careful with this, though, because these impedances likely will oscillate unless you put them in a circuit that dampens out their activity.

What did you have in mind?

If you want a big impedance in some frequency ranges, then a small impedance in others, one way to do that is to use a passive filter design. For example, the input of a bandpass filter looks a lot like the terminating resistance in the passband, and is much higher or lower out of the passband. So, the input impedance of a high pass filter made with several L's and C's will be large at low frequencies, and resistive (and smaller), at high frequencies.

I'd be tempted to use a PAL chip. It is possible to make a multiply by 4 and then divide by 10 in the same chip, which would make the total parts required to get the 4 MHz 50% Sq Wave your original 10 MHz input and a single chip.

I think you'll find that the impedance looking into a properly terminated highpass filter has this characteristic, provided that the filter is realized with a series C as the input component.

LC filters accomplish their attenuation by means of mismatch to a fixed source impedance, since they don't have any (intentionally) dissipative elements. This mismatch can go in either direction, that is, the impedance can get either higher or lower with frequency, depending on how you've chosen to realize the filter. One starting with a series C will have an infinite impedance at DC, and will approach the impedance of the load at frequencies substantially higher than the transition ("break") frequency. You can get increasingly fast impedance changes with increasing filter order.

> . . .

While that's certainly true of multipliers in general, I've certainly found it very easy to make repeatable doublers with a two transistor push-push stage. Driving it with about zero bias and a large enough signal to get it to conduct on at least a good fraction of each cycle gives plenty of harmonic energy. A collector circuit with decent Q will take care of most higher harmonics, although a simple filter following the stage is usually adequate for more demanding applications. The fundamental can be nulled out reasonably well with a pot between emitters with a grounded center tap. I'd think a push-pull tripler would be nearly as easy, but I haven't had occasion to make one.

Several simple diode and transistor multipliers are described in Chapter 5 of _Experimental Methods in RF Design_, which I heartily recommend for the homebrewer and experimenter.

Mice one Jim.
1. buy your PAL programmer
2. buy your PAL
3. learn how to obtain the required function
4. burn the PAL and discover it does'nt work
5. while patience lasts go to 2. wend
6. revert to PLL

I could do the same analysis for a PLL - it isn't a two minute job.

Do you have a problem with an XOR chip and a 74(xx)90?

Diego:

You cannot do exactly what you want, but you can get arbitrarily close to it. The "closeness" being a function of cost. The closer you want to get to the desired curve of impedance versus frequency, the more the cost [cost = total number of elements in the design].

Basically what you need to do is very well known in the network synthesis literature as driving point impedance [DPI] synthesis. [e.g. Darlington's method and other similar techniques. Darlngton's technique approaches the problem of DPI as the synthesis of a lossless two port terminated in an appropriate single resistance.] Network synthesis was widely studied and taught back in the 1940 - 1970 era but... today it is seldom seen, used, or taught. There are however lots of older textbooks which cover this field. I'll post a few such references here below.

Before you can actually perform the DPI synthesis you will first have to find an appropriate rational polynomial which approximates the impedance curve you desire to match. To obtain such a rational polynomial you will first
have to solve an appropriate approximation problem. Approximation theory and the techniques for doing this are a whole 'nother problem, and other than a few simple graphical straight line segment tricks, will usually require the use of a computer with an appropriate algorithm which you may have to write yourself! :-)

Check out the following classic texts on network synthesis for a complete run down on what you need to do:

1.) Ernst A. Guillemin, "Synthesis of Passive Networks", John Wiley & Sons, NY, 1957. [LC# 57-8886. On technical library shelves at LCShelf Call # K3226.G84. See Chapters 3, 4, 9, 10 which cover DPI synthesis in detail, and Chapter 14 which covers the approximation problem.]

2.) Norman Balabanian, "Network Syntheis" Prentice-Hall, Englewood Cliffs, NJ 1958. [LC# 58-11650. On technical library shelves at LCC Shelf Call # TK3226.B26. See Chapters 2 & 3 for DPI and Chapter 9 for the approximation problem.]

3.) Louis Weinberg, "Network Analysis and Synthesis", McGraw-Hill, New York, 1962. [LC# 61-16969. On technical library shelves at LC Shelf Call # TK3226.W395. See Chapter's 9 & 10 for DPI synthesis and Chapter 11 for the approximation problem]

One does not have to realize such designs with purely passive RLC
networks and they can often be synthesized with active RC networks
[R, C and Op-Amps] by appropriate transformations of the passive
synthesis. See for instance...

4.) Adel S. Sedra and Peter O. Brackett, "Filter Theory and Design:
Active and Passive", Matrix Publishers, Portland, OR, 1978. [LC #
76-39745. On technical library shelves at LCC Shelf Call #
TK7872.F5S42.]

Also, and I have done this a couple of times for special low frequency
applications, one can match the analog driving point impedance through
an appropriate Op-Amp reflectometer circuit to a combination analog
to digital A/D and digital to analog converter D/A and perform/emulate
the DPI synthesis in real time using digital signal procssing [DSP]
techniques.
Basically to use the A/D - D/A digital technique to emulate the desired
DPI you will have to solve the same synthesis and approximation
problems.

Hope that all helps... good luck

:-)

I am looking for a source for polyvaricon capacitors.
It seems to me that Mouser stocked them at one time,
but I can't find them in the catalog now.

Thanks in advance.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <103cqvpiefe5q95@corp.supernews.com>
Source record: 28408

Unfortunately, the question is something like how to convert a VW to a Mercedes -- you pull the radiator cap from the VW, drive it off, drive the Mercedes under, and put the radiator cap onto the Mercedes.

Harmonics are caused by distortion of the generated wave. This distortion is caused by overdriving the oscillator, which is necessary unless some other method of limiting is employed. An oscillator is an amplifier with gain greater than one whose output signal is fed back to the input. When it starts, the signal amplitude increases until something limits it. In a simple oscillator like this one, the limiting factor is the smashing of the waveform as the transistor gets overdriven each cycle. Distortion is inevitable and necessary. So, you can either reduce the distortion or you can try to filter it.

Filtering presents a couple of problems. One is that you're apparently radiating enough signal (and harmonics) without an antenna. That means that even if you had a perfect filter someplace, you still have enough energy being radiated from the portion of the circuit that's ahead of the filter. If you simply try to trap or reduce the harmonics at the collector, you might stifle the oscillation by cleaning up the waveform and eliminating the smashing.

In general, less feedback will reduce the waveform distortion. The tradeoff is that the oscillator will start more slowly, and if the feedback becomes too little at some temperature or battery voltage, it'll stop altogether. But it you'd like to try this, fiddle with the values of C1, C2, and C4. I believe that decreasing C1 or C2, or increasing C4, will reduce the feedback.

If you want try improving the collector waveform, increase the Q of the tank by decreasing L1 and increasing C6 to compensate. Or you can try putting a series LC network (with fairly high L/C ratio) from the collector to ground, tuned to the second or third harmonic, to act as a trap for one particular harmonic. Any of these schemes could make the oscillator stop, though.

A professional approach would be to add a buffer stage, and build the oscillator and buffer in a shielded box, with good filtering on any lines going in or out except the output signal conductor. Then, a filter at the output would be effective, so one could be designed to take care of the harmonics to any extent desired.

I'm not sure if I understood your question. You want a filter " which
decreases
"slower", for frequencies close to zero but then decreases "faster" for
higher frequencies.
I take it you want a transmission (starting from DC) a curve that "slowly"
decreases until a top point (the resonant freq.), and then falls quickly !?

A second order (or higher polynomial) Butterworth filter will do that for
you.
It has a transmission of Vout/Vin = k/(s^2 +bs+c)

where b is the ratio of the steepness Q (decrease of impedance) to the
resonant frequency.
c is the reciproc of the squared resonant frequency [1/ (w^2)] w-
radians.
k is a scalar - the DC amplification

Now what is the resonant frequency in your question ?
-It is the point where the transmission "decreases" in both direction (the

top point).

You would find a well suited circuit description in textbooks explaining about the "Sallen Key" set up. It uses one op-amp, two capcitors (one in the positive feedback !) and three resistors. It even works !

(^ - means squared)

Okay. I can't agree that they are "easy" after having enough
occasions to make several. :-)

Your mileage, of course, varies.

>Several simple diode and transistor multipliers are described in Chapter
>5 of _Experimental Methods in RF Design_, which I heartily recommend for
>the homebrewer and experimenter.

A diode doubler using a toroid transformer, pair of diodes and a tuned
circuit in the output works fine right off the paper pad and slide-rule (or
calculator) numbers. Typically the source is a distorted sinewave
from either another multiplier or an oscillator. Rocket science it ain't.

BREADBOARD. A most handy part of the bench tools. Recommended
first. Especially for those purist hobbyists who think that digital
circuits
aren't "real radio." :-)

Playing with bias on a transistor multiplier stage is fine for optimizing a multiplication but all it is is play when there's nothing to compare one bias setting with another as to power output at the desired multiple. A spectrum analyzer isn't an absolute need, by the way, there's other ways to measure the harmonic content. Is that in "Experimental Methods..." published by the ARRL? [I'm pushing work-on-the-bench, not books, pardon my attitude that has resulted from years of having to produce hardware results, not paper reports]

>impedance (Abs) raises as the Frequency approaches zero. As a formula: Zin
>= 1/(1/R + i w C) , where i ist the imaginary number and w the frequency.

"Everyone" doesn't know that. You have the basic formula for
ADMITTANCE, not impedance. Let's clarify some terms first. The
admittance of a simple parallel R-C is more commonly written:

Y = (1 / R) + j (omega x C)

Where: Omega = 2 x pi x frequency in Hz, the whole quantity
often referred to as "radian frequency"

The "j" is used in electronics in place of the lower-case "i"
for the imaginary part of a complex quantity. Electronics
folks do that to avoid confusion with AC current normally
written as "i".

To find the impedance, take the COMPLEX INVERSE of admittance
to get impedance from the identity:

Z = 1 / Y = [a / d] - j [b / d] where:

a = real part b = imaginary part

d = denominator = a^2 + b^2 [sum of the squares]

For the final equation the impedance of the parallel R-C is:

a = (1 / R) b = (1 / (omega x C)) and

d = [R^2 + (omega x C)^2] / [omega^2 x R^2 x C^2]

or, in final form:

Z = [(omega^2 x C^2 x R) / (R^2 + (omega^2 x C^2))]

- j [(omega x C x R^2) / (R^2 + (omega^2 x C^2))]

Like it or not, the above is what tens of thousands of electronikers work
with every day worldwide. Obviously one can do some approximations
for real-world applications where the errors are allowed to be kind of
gross, but that depends on the (unspecified) application.

>Now the hard part. How does one create an Impedance, which decreases
>"slower", for frequencies close to zero but then decreases "faster" for
>higher frequencies, than the simple parallel RC-Circuit?

At very near DC, the impedance is governed by R since the reactance
of C is going to be so high that it becomes one with the dielectric
material all around.

The "rate of decrease" of impedance is governed by the value of C.
Graphed, it begins at pure R and then decreases at a slope
governed only by C..

>Is there some kind of procedure like the one for syntesizeing LC-Filters
>(Butterworth, Chebychev,..)?

First of all, the procedure should be to get the terms correct. From
there on, it is some grunt work with a scientific calculator.

Suggestion: For those who use an HP 32S II programmable with
long-term power-off storage of program and constants, I keep 2 x Pi
in constant storage in register T for handiness in getting radian
frequency values. A recall and multiply by frequency yields "omega"
which can be stored in register W. Easy to punch through the
numbers that way.

>Simply increasing C does not really help, because this equals a factoring of
>the frequency.Increasing R does not help as well, as it seems.

Simply increasing C most definitely sets the higher frequency impedance.
There's nothing else in there in a two-component circuit that is frequency
sensitive...except for the Q or quality factor of the capacitor and lead
lengths of components. If one needs to get very fussy, there's always
a SPICE analysis where everything can be modeled, lead lengths, stray
capacity, everything.

Yes, modern network theory can make all kinds of impedance-varying
circuits with many parts and there are many, many textbooks on the
subject, all costing much money. In order to use all that material, one
has to know the difference between impedance and admittance and how
to convert from one to the other.

Yes, that book is published by the ARRL. Its authors, Wes Hayward, W7ZOI; Rick Campbell, KK7B; and Bob Larkin, W7PUA have, unlike so many authors, spent careers doing just what you and I have had to do -- produce hardware results. Of them, I know Wes the best, having been friends with him for about 30 years. After a stint at Boeing long ago, Wes was a design engineer in the spectrum analyzer group at Tektronix for a number of years, where his designs were incorporated in a number of state-of-the-art spectrum analyzers. He went from there to TriQuint semiconductor, where he designed many RF components which are in daily use in probably millions of cell phones and other wireless products. He recently retired and has been doing some consulting. His publications in amateur journals, spanning decades, are legendary and many are seminal. I don't know Rick quite as well, but he's also a very capable and accomplished engineer (in spite, one might say, of his Ph.D. and period in academia). For years now, he's also worked as a design engineer at TriQuint. To get a feel for his approach to solving real problems, check out the articles he's published over the years in QST on phasing type direct conversion receivers. Bob I don't know at all, but Wes speaks very highly of him, and I have absolute confidence in Wes' judgement of skill.

There's nothing in that book that hasn't been built and tested, and designed to be repeatable. And everything has been designed by people who really know what they're doing. This isn't a book of kluged-it-up-on-the-bench-and-made-one-work-once projects as so many are. I'm sure that if you'd take a few minutes to look over the book, you'd immediately recognize that.

To answer your specific question, I don't, in a brief scan, see details in the book about optimizing the bias for maximum harmonic content of the multipliers. Most are diode multipliers anyway, with no bias

adjustment. The book covers a very wide range of topics, and the section on multipliers consists of only a couple of pages of text. There is, however, a chapter on simple test equipment a homebrewer can build, including a brief description of a practical spectrum analyzer. Wes did, incidentally, design and publish such a thing some years ago. I think it's still available in kit form from Kanga US.

I've also spent a career having to produce real results. But apparently our approaches differed, because I've found that good paper designs, often aided by fundamental knowledge gleaned from books, lead to good hardware results, rather than being an opposing and somehow inferior method. And they have the advantage of being well understood, predictable, and repeatable.

Well, true... Happens I have access to that sort of thing, but I do see your point.

Another approach might be to divide by 5 and then you can double twice with a couple of chips, and then divide by 2 to get the 50% duty cycle.

A PLL system works, but for something this simple a couple of generic glue logic IC's will serve the purpose.

Let me see, it'd require a 7490, a hex inverter for some delay in the multiplier, and a 7400 nand. If memory serves, that ought to do it.

1431. looking for rf design book

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-21 07:20:40 UTC
From: gobo20@lycos.com
Message-ID: <f6a54aa0.0402202320.5bd55668@posting.google.com>
Source record: 28418

Does anyone have any book recommendations of a "cookbook" for RF design? Cookbook might not be the best word. Something that covers network design, S-parameters, filters, Smith charts, etc. Something without the calculus! I had all this in school (oof, 25 years ago) and didn't retain it because I've not used it. Now I have an amateur license and want to just play with vhf and uhf circuits. I want to do things right, but don't want to have to go back and audit three calculus courses to remember how to do LaPlace transforms. (Yeah, someone's going to say "you gotta" and I know that, but I want to play with the electronics and not spend months on the math.)

Thanks.

Indeed. Occasionaly new not-yet-understood phenomena are discovered
on the bench, but the art benefits greatly from a detailed
understanding of the underlying mechanisms. Coincidently, I was
browsing "Inventions of Opportunity" this afternoon and stumbled
across an article about how in the late 1950's a newly-developed high
speed sampling scope aided in understanding harmonic-generation
mechanisms in diodes, which apparently helped a lot in the development
of step recovery diodes. Before that, apparently there wasn't good
understanding about why some diodes generated lots of harmonics and
others didn't. Step recovery diodes are optimized for fast turn-off
of the reverse recovery, and are used in generating a "comb" of
harmonics. It's not uncommon to pick off the desired harmonic with an
appropriate filter, up to beyond the tenth harmonic. Seems like step
recovery diodes are not in as great favor as they once were, since
there are generally better ways to generate higher order harmonics.

With a little understanding of the spectrum of a non-symmetrical
square (or trapezoid) wave, it's not hard to come very close to an
optimum bias and drive for a given harmonic output in an amplifier
stage. If you do it just by experimentation, you're liable to find a
local optimum that's quite a bit worse than the global optimum. Same
with the output coupling/filtering network.

Cheers,
Tom

Good news: to "do things right", you don't actually "needta" revisit those courses. Their uses in RF design would be far too specialized for what you need right now.

What you need much more is the basic knowledge that qualified you to take those higher courses... and even after 25 years, I bet that knowledge is still with you. Simply being prepared to plug numbers into formulae, and maybe transpose a few variables, will take you a long, long way into RF design.

So... just explore, follow your instincts, and the math you need will come back to you.

Although not an RF design text, 'The Art of Electronics' by Horowitz and Hill is an excellent example to how to use math when you need it, while always avoiding unnecessary 'math for math's sake'.

Some areas do require math because they're fundamentally math-driven, for example complex modulation and DSP techniques - but even there you can understand a lot from an *appreciation* of the math (by which I mean the ability to understand where it's going, as distinct from the ability to do it yourself).

The huge advantage of being an amateur is that you don't need to go into areas that require knowledge you don't possess. The *other* huge advantage of being an amateur is that, if you decide that's where you want to go, then nothing is off-limits!

RF design, now... to get yourself started, try Bowick (sorry, I can't remember the exact title, but the name will find it) and also Hayward's 'Introduction to RF Design' (now published by ARRL).

The other growing-point in RF design is the use of computer-aided design and analysis. Gradually, radio amateurs are moving towards this approach, where you spend quite a lot of time designing, but don't

switch the soldering iron on until quite late in the process. Seek out books that use this approach (but avoid books that are too closely tied to any specific brand of software). There are lots of free 'student version' software downloads on the web, but that's a separate large topic.

Finally, pick up an old copy of Terman's 'Radio Engineering', to keep yourself in touch with the days when it all had to be done using algebra on the bare metal. That demanded a very fundamental level of understanding, which is in danger of becoming lost.

Getting a bit off-topic here, but as of a few years ago, we were using step recovery diodes to generate the step in high speed TDR systems, and to generate the strobe for the sampling gate in high speed sampling scopes. Rise times were on the order of 7 - 15 ps (bandwidth up to 50 GHz or so), limited primarily by circuitry external to the diodes. SRDs replaced tunnel diodes in earlier generations of instruments. I've been out of touch with that class of instruments for a few years now -- do you know if something has replaced the SRD for generating fast steps, or just for harmonic generation?

Buy one at Radio Shack for about $10. I got one for my very hard of
hearing M-I-L who really loved it. I rigged a light next to her TV. When
it flashed, she answered the phone. Her hearing aid was designed to
receive signals from an inductive ear piece in the phone.

What sort of performance is required? Diode mixers are easy to obtain
and have good IMD characteristics. The impedances on the ports need to
be properly matched.

"Good." :-)

>Diode mixers are easy to obtain
>and have good IMD characteristics. The impedances on the ports need to
>be properly matched.

What - the sort of crossed diode config one often sees in the ham
design books? Do you think I might as well just make one up from
discretes? I'm basically just trying to combine 60Mhz with 20Mhz to
end up with the difference frequency in this case. JJ suggested a
chip, but looking at the data sheet, it seemed to be designed more as
a modulator than a mixer. Let's not get into an argument over
semantics but y'all know what I mean, I'm sure.

BTW, thanks for a good steer with the Pulsonix suggestion, Leon. I'm
making good progress getting to grips with it.

Sounds like "Experimental Methods in RF Design", published by the ARRL is
what you are looking for. Its a pretty useful book, without going much over
algebra (but is useful even if you don't want to use much math).

>Is the type of distortion critical? How about a clipped/clamped
>sinewave?

Yes and no. :-) A quantitative answer isn't possible since the
waveform must be described accurately in shape (or spectrum
analyzed) in order to determine the harmonic content. Suffice to say
that a square wave cannot be used with a passive diode doubler; all
the energy is contained in the short transition times and that is rarely
enough to be worth it.

If an untuned oscillator output is to be doubled, that scoped waveform
will quite probably look distorted. Such is quite likely to be a good
harmonic content source for a passive diode doubler. The obvious
alternate is to tune the oscillator output to the second (or third)
harmonic right off... :-) I mentioned diode doublers because (1) they
are passive; (2) they are relatively broadband; (3) common legacy
fast diodes such as 1N914 and 1N4148 can work in that application
beyond 20 MHz; (4) they work with cylindrical-shape coils also but
toroidals forms make the whole circuit physically smaller.

If the source's impedance is too high to handle a passive diode
multiplier, then an active-device multiplier is a better choice. [at this
point it is a promotional insert time to publicize ARRL publications
of "tried and proven circuits" provided one copies ALL the parts of the
circuit exactly as shown to be tried and proven...:-)]

The original thread question was general enough that the number of
variables would fill a shopping cart. Quantitative answers to such
questions aren't possible. At best, only suggestions of a general
nature can be the answers.

Digital logic off-the-shelf is excellent for making things right off the
paper design because they work with two stable states with very high
transition times; stay within the rise, fall, and propagation times and
fan-out rules and it should work right off the scratchpad. Analog

circuits are a whole new game with different rules and a large number of unknowns even if some detailed specs are available.

For one-of-a-kind homebrew applications of analog multipliers, I'd say it was time for experimental bench cut-and-try work first. A paper analysis is going to take TIME even if the smarts are there. Empirical data derivation (cut-and-try) is quick, much quicker than the paper chase. I say empirical since the supply voltages may be different than some book example, few have instruments for measuring source and load impedances or spectral content and power level of the source.

The simpler the prototype-idea circuit, the easier it is to make a stock kind of circuit on the bench and probably characterize it over a wide frequency range and, possibly, with varying supply rail voltages and power levels. Heh...a LOT of production circuits were engineered that way even though the companies who made it came along after and made them look like seven wonders of the world in PR literature later. They were after _reproducible_ circuits in _their_ systems, not as shining textbook examples. Some passive component values may have been selected to reduce the overall type-of-parts count by using "common" values needed in other circuits. That's perfectly acceptible as long as a circuit works and can be reproduced...at a profit. :-)

Can I answer your original question? Not really. Think of a passive diode doubler as a full-wave rectifier. Those take a fundamental sine and "double it over" (negative swing made positive through trans-former) to make two half-sine pulses of the same polarity for each full AC cycle. There's a lot of "second harmonic" in that rectifier output...which makes for easier filtering since the ripple voltage frequency is twice what it would be for a half-wave rectifier. Using fast legacy diodes at a much higher frequency turns out to be the same sort of thing. Unlike a rectifier circuit, the output of the doubler can be tuned to that second harmonic (a no-no for most power supply rectifiers) to get the most output. You could use a clipped sinewave input, but why and where is the clipping done and what extra circuits or components are needed to justify that?

I've only outlined SOME of the mental questions each brewer has to make for themselves. Concentration is needed for application.

==========
SA602AN as well as SA612AN each costing GBP 2.50
Both have on-board LO circuit.
www.modecomponents.co.uk ,probably also from www.jabdog.com
Both companies are in the Birmingham area.
If you are a member of G-QRP Club the SA602AN is somewhat cheaper from Club
Sales.

I wholeheartedly agree about Horowitz and Hill, mine is never very far
away. In teaching basic circuits to coworkers (I'm in data processing
now) I tell them that if they must get only one book ï¿½ that's the one.
I wish the guys would do a third edition.

Message-ID: <c18igb$gm1$1@hercules.btinternet.com>
Source record: 28441

For given ground path distance and height of reflecting layer this program
calculates elevation angle, angle of incidence with the layer and the
radio-path distances for one and two hops.

The program then gives an insight into how the various losses are
proportioned along the radio path. A 100-watt transmitter is used at one
end of the path with a receiver + S-meter at the other.

Download in a few seconds program TWOHOPS from website below and run
immdediately.

The Philips SA602 or SA612 ought to be available in the UK. Don't overload the RF port though, the gain folds back over 200mV RF input -- confuses the hell out of an AGC loop.

I do this with a dual gate MOSFET, osc on second gate, signal on first.
A voltage divider on gate 2 to set it in teh non-linear part.
This works very well, is not critical, very cheap and extremely reliable.
Also the noise figure is good.
So tuned 40MHz in drain
I did one some weeks agao, but cant remember what that was for?
Anyway that sceme works up to a GHz , from kHz up.
If you need diagram and part example I could draw up one here.

Hey Tom, There was a question exactly the same as yours within the last 6 mnths to perhaps 1 year ago. I do remember that the thing won't even oscillate at all with out one of the currents present (Tune/FM), It is a coil, and needed about 10 mils I think, plus the normal B+/GND voltages.

?? Lots of energy in the fundamental; filter to extract the
fundamental and feed it to your full-wave rectifier doubler.
Efficiency can be high if the filter does not cause dissipation in the
source at the harmonics.

Greetings- I have one in a high level transmitting mixer I built in about 1960. The mixer took about ten watts in on 14 mhz from my HT-32B, mixed it with the output of a crystal oscillator, drove the grids of the 829B ,and the output was 144 mhz ssb, enough to drive a 4X-150A amp. The circuit was designed by Don Stoner, W6TNS, and published in CQ mag., as I recall. The tube was used in VHF military gear . It has a little brother, the 832A.
Jim, K8JL .

1464. Power Inductor Optimization...

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-22 05:11:22 UTC
From: nospam@nowhere.nil
Message-ID: <hobg30hjjt4rr4c29b251ittavjgpus4rj@4ax.com>
Source record: 28301

This is not directly HAM releated,
but Ham radio is used in the project.

I'm building a Solar powered RC plane.

In that plane I have 6 different solar cell planes.
For each plane I'm building a maximum power point tracker.
The heavest component of the MPP is the inductor.

I need the lighetest most efficient inductor possible.

Specifications

30uH min, 50uH prefered.
6 amps DC current max.
7 amps peak current max.
50 to 150Khz switching freq.

(The current ripple has to be low in releation to the DC current to
keep the solar cell in the "Sweet" spot.

Inductor can not be bigger than 100mm in diameter and 25 mm thick.

I'm thinking I want a Aluminium wire air core toriod, but I'm not
sure.

The weight trade off:

At the point of marginal flight. (About 3 amps in the inductor)
Weight is at an absolute premium. I can trade one watt of inductor
loss (at 3 amps) for 190 gm of mass.

Assuming 12 Ga wire in a cylindrical core 4" in diameter:
12 Ga two layers of 10 turns each gives about 45uH.
251 inches of wire for a wt of: 57gm
and a DC loss of: 1/2 W at 3 A and 2 W at 6 A

I'm a bit lost here .... any suggestions on how to proceede?
Should I consider using a toroid core?
Adds weight, and switching losses, but reduces the total feet of wire
and thus the weight.

It would be a lot easier of solar cells were not low voltage high
current devices... alas they are.

Tom, look at it this way... Draw the square wave, assuming capacitive coupling so it has a zero crossing. Then draw the same signal but invert the negative going half to positive, which is what the full wave diode doubler would do.

You wind up with a positive voltage, but with VERY narrow negative spikes.

So, a square wave into a diode doubler will produce only a small amount of the second harmonic. You'd be better off running the input square wave through a lowpass of some sort and then doubling it.

Given a sine wave input, there is a fair amount of negative going signal and that is what produces the high energy content of the second harmonic.

You could make your own, but an MCL TUF-1 or SBL-1 won't be all that
expensive. They do need a 7 dBm local oscillator drive level.

A powdered iron toroid inductor may be close to optimum from a weight standpoint. Check out these part numbers from Digikey:
125 uHy @ 7.77 ADC, .032 ohms, 46 mm dia, 19 mm high, M5716 (the data sheet may have the weight)
34 uh @ 6.4 ADC, .026 ohms, 22 mm dia, 14 mm high, M9797
63 uHy @ 7 ADC, .037 ohms, 29 mm dia, 17 mm high, M9823

>What's a doubler based on the good old 1N4148 good for, top end
>frequency-wise?

made some experiments 10-15 years ago with doublers to 144Mc/s, and
they probably would work on at least 200Mc. Best experience with a
BFR90 amplifier following the 'rectifier', see
http://home.online.no/~la8ak/c13.htm
It was important with certain dc load following the diodes and some
bias current

Another interesting multiplier used for 100kc calibrator - on vhf -
described in UKW Berichte uses quad nand schmidt trigger, where the
input signal is splitted - one part to a nand input and the other to
3x nand gates connected as inverters and connected to the second input
of the nand-gate such that the truth table said constant logic high
output, but a very thin spike occured because of the transition time
delay

Since you don't specify anything important like IP3, my recommendation
is Siemens S042P. Earlier, when Motorola was easy to buy from, I would
have used MC1496P, but none of them have high IP3 and I suppose NE602
isn't any better. If balance isn't important, I would use BF905 or
BF199

1470. TS-118A/AP, RF Wattmeter/Dummy load

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-22 13:35:55 UTC
From: "owen.home" <owen.home@ntlworld.com>
Message-ID: <Ee2_b.18085$ft.16663@newsfe1-win>
Source record: 28307

Hello
I recently went to buy an RF sweep generator and ended up bringing home a TS-118A/AP (Bird) RF wattmeter, as one does! I have some questions:-
1. Given that the RF power sensors for the various bands/power ratings are added external to the meter with only the coax connecting through to the unit,how does it work? I assume the sensors are thermocouple types but there's no separate DC circuit and I can only see a narrow constriction in the sensor with the centre core being a very fine wire.
2. I'm missing the calibration/multiplication factor graph for the MX-1784/U sensor, would anyone have one they'd be prepared to scan and email for me? Any pointers to a full manual on the net would be good also.
3. Although the unit is marked 20-1400MHz at 500W, the MX-1783/U graph shows power levels up to 1200W at 40MHz, I guess the unit is very conservatively rated but does anyone have true figures (not that I intend to work at that sort of power levels).
4. Is it OK to use as a straight dummy load without the sensor, I've tested it at 2m and it seems fine but why the 20MHz lower limit? also it doesn't measure 50 ohms at DC so I guess it can't be a straight resistor so what's the load?

I'd appreciate all and any information you can give about the wattmeter, it's not something I'd have planned on buying but it looks like it'll serve all the needs I'd ever have for a high power dummy load/wattmeter other than for the lower HF bands.
Thanks in advance
John

The MX-1784 is a tuning shunt used for safety reasons
on transmitters with capacitively coupled outputs.
>3. Although the unit is marked 20-1400MHz at 500W, the MX-1783/U graph shows

The manual speced power levels are.

Range 20- 1400mhz
power 20-100mhz 2-300watts
100-300mhz 2-500watts
300-750mhz 2-125watts
750-1400mhz 2-125 watts
>4. Is it OK to use as a straight dummy load without the sensor, I've tested

The lower 20 mhz limit is to prevent damage to the metering circuits.
It can be used to DC if you disconnect the metering circuit.
I learned the hard way!!!!!

It is a straight 50 ohm resistor in the oil. If you measure anything
much differnet the resistor is defective.

Do the dual gate mosfets outperform the NE602 with regards to IP3?

For some reason the NE602 refuses to oscillate with crystals but LC's are OK.

Gene
Many thanks for the reply, I understand now - the meter is across the line
but isolated at RF with an inductor so that at DC I'm seeing the meter and
load in parallel, mine measures fine with the meter disconnected.
Thanks for the warning about damaging the meter below 20MHz and the info on
the MX-1784/U, I opened it up and can see the inductor to ground.
I'd still like to know how the sensors are made up though and I would
appreciate a copy of the manual sometime if you get a chance, I'm missing
one of the sensors - are they easily available these days?
Thanks again
John

[snip]

The NE602 only supports Colpitts and Butler crystal oscillator
configurations. It is *not* an inverter-style oscillator.

Sorry. If you are using the passive diode doubler looking like a
full-wave rectifier circuit, and you have a symmetric square wave,
the only harmonics you get are from the transition edges.

Symmetric square waves have very low even harmonic energy
content; harmonics are in the odd harmonic frequencies.

A non-symmetric rectangular (not a 'square') waveform has more
even-harmonic energy content.

Right on, Jim. "Filter to extract the fundamental and feed it [the
fundamental] to your full-wave rectifier doubler." Of course, third
harmonic mixed with fundamental gives you second and fourth, etc., so
there's a hint that the harmonics could be useful if the phases were
right. What do you get if you feed a mixer a square wave in one port,
and the same square wave delayed by 1/4 period into the other port?

Cheers,
Tom

Thanks to Jan-Martin for his reference to some actual experiments.

But in reply to Paul, I'd ask: Do you understand how the "full-wave rectifier doubler" works, basically? (Ideal waveforms and all that.) Do you have a data sheet for the 1N4148? What items from the data sheet do you suppose might limit the useful frequency? Can you make an estimate, based on the data sheet numbers? What would you do in a design to extend the frequency range for a given diode characteristic? For example, what does diode capacitance do to circuit operation? What does reverse recovery do? In the full-wave frequency doubler circuit, what does the input impedance look like, assuming an ideal transformer, when one diode is forward biased and the other is reverse-recovering? Can you think of parts to add to cause that to not be so much of a problem (assuming it is a problem)?

Thinking about this sort of thing is useful not only in figuring out what to expect, at least ball-park, but also in getting better performance out of someone else's circuit and/or understanding its limitations.

Cheers,
Tom

1487. AGC - why delayed? good properties?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-23 03:21:44 UTC
From: Tom Holden <holden_family@sympatico.ca>
Message-ID: <dle_b.3267$Mo4.118176@news20.bellglobal.com>
Source record: 28325

In researching desirable AGC characteristics that might be applied to the RS DX-394 over a year ago, I came across the terms 'delayed' and 'hang'. Thought they were interchangeable but on reading the ARRL 2004 Handbook, it seems that 'delayed' means that the attack speed on the RF stages is slower than on the IF stages or is relatively delayed. According to the HB, "This prevents a premature increase in the receiver noise figure". On the DX-394, I found and removed an electrolytic capacitor in the AGC line of the RF stages that has the effect of slowing the attack relative to that of the IF. Can't say I hear any difference with it out. I would have thought that we would want the AGC attack to be fast on all stages in order to avoid momentary overload.

I concluded the following to be good targets for AGC behaviour after surveying a number of radios - corroboration or otherwise appreciated.

Attack: 1-13ms
Release:
- fast: <25ms
- medium: ~300ms
- slow: 1.8-3 seconds

I thought the fast release to be too fatiguing for human listening to SSB speech and ICW code but desirable for machine decoded data formats to minimise loss of data. Also, with audio derived AGC, the distortion on heavy bass modulation of all AM modes would be excessive.

In applying mods to the DX-394 by others and some designed by myself, stretching the release time towards the 'slow' target has the side effect of lengthening the attack time to potentially a few hundred milliseconds. My version is the fastest so far with an attack of about 100 ms on a release of 2 seconds. I'm wondering if there is much to be gained by struggling to bring that down to the target of 1-13 ms.

Comments on my assumptions, logic, conclusions and questions most welcome!

TIA,

Tom

If you have Ghostscript or some other PostScript viewer/printer, it should
be pretty easy to produce the scales in PostScript. PS is really adept
at drawing simple geometrical objects (draw an arc here; draw a line
at 203.5 degrees from the vertical here; etc.) and it should be easy to
put together a scale. Something like...

/radius 100 def % radius of the dial
/startscale 100 def % "zero" (leftmost) reading

Of course, you might want to fiddle with that to get a particular look.
You could put the labels on in PS also, but it might be easier to
import it into some other program and apply them there.

IFAIA, pretty much the same as a full-wave rectifier in a PSU. All the negative going half-cycles are converted to postitive going half-cycles that 'slot in' between the unmodified positive half cycles. The resulting waveform is twice the original frequency and subsequent signal processing can restore this half-wave signal back to a full sine wave of the desired output frequency.

>Do you have a data sheet for the 1N4148?

I could get one off the good old 'net. Aw, fuck it; I'll get one. Hang on a minute..... Got it!

>What items from the data
>sheet do you suppose might limit the useful frequency?

Primarily junction capacitance, I guess. In this instance, 4pF. There's also something called transit time, IIRC, which is relevant, but for some reason it's not mentioned on the DS.

>Can you make
>an estimate, based on the data sheet numbers?

Nope. Maybe from the graphs, though...

>What would you do in a
>design to extend the frequency range for a given diode characteristic?
> For example, what does diode capacitance do to circuit operation?

More slows it down.

>What does reverse recovery do?

Slower recovery the same, I guess. I'm not totally familiar with this parameter but it would make sense.

>In the full-wave frequency doubler

I always thought "delayed AGC" means that there's no gain reduction
unless the strength of the incoming signal reaches a certain threshold.
It's not a delay in time, but in amplitude.

Consider using a faster switching chip -- this reduces the amount of inductance you need to store energy.

Don't try to minimize the ripple -- optimize it. This will also allow you to use smaller parts. Also, carefully select the ESR and inductance of the filter cap for the application -- at a high frequency the filter cap will also look like an inductor. All trace lengths add inductance = impedance = loss of energy.

You can get 1 MHz chips from TI, National, Linear Tech etc. I myself haven't used a chip above 100 kHz, so would suggest that you peruse the manufacturer's data sheets for an appropriate PCB layout.

Source record: 28330

Dr. Ulrich Rohde described in one of his articles (QST ?) a novel
product
detector based on CD4066 MOS-switch, which is supposed to have a
superior
performance compared to other types. I have tried the schematic and
found the distortion quite unacceptable.

I have not found any other reference to this type of product detector
and may have misunderstood the cocept somehow. Therefore I would like to
know if this idea is still alive and/or if somebody has any experience
of it. Otherwise I will rely on either DMB or MOSFET in my homebrew
receiver which is intended to be an advanced .
project.

I have already successfully constucted the front end with Fairchild
FST3125
switching mixer followed by a strong postmix amp, 12-pole xtal filter
and the following if-stages. It would a shame to destroy the whole thing
with an inferior detector/af-portion when I am trying accomplish
something better than my previous
design which is heavily based on the W7ZOI Progressive receiver.

here is the first mention of IP3 in the thread, I've asked whether it
is important or not, but have not received any confirmation and will
therefore not comment. If IP3 was said to be important I am aware of
other mixers, and have used some douzens SBL1, SBL-1X, CM-1, SRA1 and
other since 1977. A very easy mixer to use is TBA120=SN76660N.

I usually construct to requirement, not what somebody else think is
fine

There are multiple losses here.
MY nominal array voltage is about 7V my converter is boosting to
10 to 20 V (Depends on the amount of solar power availible and the
loading conditions on the prop/motor)

So if I run a normal boost converter with a good Shotkey diode I get a
drop of 0.4V or 4% (at 10V) of my total power goes into the diode
drop. So I am using syncronous rectification.
I can't find a highside fet driver that will efficently run much
faster than 100Khz.

I've thought about (mis) using one of the low voltage syncronous
buck converters and running it backwards, but the the chips are
generally too smart about startup and the error conditions and current
sense choices are wrong.

The easiest is a neon bulb NE-2 [don't use an NE-2H] and the largest resistor to get it to light. Probably in the 10's to 100k. This isn't bright, but needs no power. This was used for many years in many circuits.

If it is not bright enough, then one of the other circuits with a high resistance sense and external power to light a bright light is needed. That link has one

Heikki,
I'm not sure exactly what this particular circuit looks like, but I strongly suspect it's just a balanced mixer made from 4066 analog switches. I have used this technique and it is quite good at low IF frequencies (a few MHz or less). Are you sure you have the switches biased properly? The thru-path should be biased at about 1/2 of the 4066 DC supply voltage in order to avoid severe signal clipping. Can you point to a link where the circuit is shown??

Tom,

The term "Delayed AGC" originally referred to the fact that the AGC
action (reduction of gain) does not occur until the received signal reaches
some signal level and NOT to a time delay. I believe this is to allow the
signal to get up to a desirable level at the detector before any gain
reduction occurs, otherwise it won't get to "maximum" level at the detector.
AGC time constant is quite a personal preference and also depends on
different conditions. I prefer slow AGC to prevent pumping and the annoying
bursts of noise between SSB syllables, but if QSB is fast, this can loose
syllables.

If you have a very high-Q tunable front end filter, you usually get
away with a mediocre IP3. However, if wide open (1 octave) front end
filters are used, you would benefit from a high IP3 if you are using a
decent antenna.

If you try to receive the 7000 .. 7100 kHz amateur band in Europe,
with 100-500 kW broadcast transmitters every 5 kHz starting at 7105
kHz, the input IP3 number would have to be at least 20 dB higher than
the strongest broadcast signals or even 30 dB higher if you try to
receive QRP stations.

Attenuating the whole antenna signal with a passive attenuator will
also rapidly drop the IP3 products, but sooner or later the weak
desired signal will be lost in attenuator thermal noise.

1506. Soldering Tips that Heat Very Fast

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-23 19:57:52 UTC
From: martin@okstate.edu
Message-ID: <c1dm00asb1@hydrogen.cis.okstate.edu>
Source record: 28346

As a ham who happens to be blind, I have been soldering for
near 40 years. Yes, it certainly can be done, but it works best if
one does a few things differently.

One thing that helps a lot is if the soldering appliance such
as a soldering gun heats very fast. This lets you position everything
safely without burning either fingers or the work before applying
heat.

The first soldering I ever did was with a Weller gun. They do
heat relatively fast and let you put the tip where it needs to be just
as you pull the trigger.

My all-time favorite soldering tool for small work is the Wahl
cordless gun with the smallest tip they sell. I believe it is called
the Wahl Isotip.

This brings me to my question. Is there anything else which
has come along that heats a small tip rapidly, the faster the better?

I have even tried one of Radio Shack's butane-powered
soldering irons. They certainly work, but the experience is similar
to a continuously-on electric iron except one must be mindful of the
little flame inside the screened-in area at the tip base.

There was recently some discussion on the blind-hams mailing
list I am on about this topic and I thought I'd check to see if
anything has changed.

My only gripe about the cordless guns is that the nicads go
bad after two or three years and it is necessary to replace them.
Of course, the task of replacing them is a drag in that the challenge
is that of getting everything back in the case exactly the way it was
before. It can be done, but patience is very much in order.

1507. DDS 50 ohms buffer ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-23 23:07:12 UTC
From: lepton@sympatico.ca
Message-ID: <399debb7.0402231507.3a5a11c1@posting.google.com>
Source record: 28342

Hi.

I try to figure out what can be the amplifier that can match the AD9835 300

ohms output impedance to 50 ohms with a gain of about 8 db at 13.5 Mhz.

Is this can be done with a simple transistor or a monolithic amplifier ?

I have take look on the net and they always use it unbuffered !

Thanks in advance for any information.

Gillis

Gillis,
Most of the Analog Devices DDS chips have a current-source output. This means the DDS source impedance is set by an external load resistor (Rout), making it somewhat arbitrary. I'm using 50 ohms in my unit. The peak RF output voltage will be Idac x Rout, where Idac is the DDS DAC current.

As far as an amplifier is concerned, the choice is somewhat dependent on the application. If the load circuit is fairly 'stiff' and is not real sensitive to the source impedance, you can use a MAR monolithic amplifier (Mini-Circuits or Avantek). However, these can become unstable when driving reactive loads, and they also have poor reverse isolation, which means that load changes could affect the frequency response of the DDS lowpass filter. Also, you want good linearity, otherwise the waveform will become distorted and the harmonic content will increase.

You might want to look into some of the ultra-wideband opamps that are available from people like National Semiconductor.

Hmmm...I know that there are other ways to generate sampling pulses in
things like (ultra) fast sampling scopes. I suspect that similar
techniques can be used for fast edges. What little I know about that
area I can't really say much about.

After my SRD posting, I reviewed a little more in the Inventions of
Opportunity book. The late '50's fast sampling scope article
mentioned that the HP Labs researcher who saw the diode recovery
phenomenon went on to gain understanding about the mechanism involved,
and presented a paper about it at one of the semiconductor
conferences. A couple articles later in the book there's one devoted
to SRDs. They show a *20 frequency multiplier in one stage using a
SRD. Net efficiency can be pretty good, with the proper design. Just
don't want to be actually dissipating the energy that's in all the
other harmonics.

Cheers,
Tom

Yes, this is correct for the proffesionals, a certain amplitude level
must be reached before the AGC threshold is hit, while amateurs
started to talk about time delay, rise and fall times when AGC was
optimized for SSB reception. But even receivers designed before WWII
had some degree of mode-dependent time delay optimization, fast for AM
and somewhat slower for CW
I experienced the importance of proper time constant when I tried to
improve the Collins 51-S, see http://home.online.no/~la8ak/b35.htm

Where I live, in the woods of Maine, we have power outages.

Solar panels and all that stuff is quite expensive, but old car batteries ("old" is when it doesn't get my Diesel started in subzero temps) are not.

To make things just a bit comfi it would be nice to leave it in place with a charger attached (right now I tote the charger around when needed).

Many things will run right off the batterie(s), others might need an inverter.

So basically I am talking about a photovoltaic system without the photovoltaic panels, sort off.

So which chargers can I leave permanently attached to a battery?

The word 'trickle charger' or 'shore power' comes to mind. How is that different from my old Sears charger which does me good for many years already (but I unhook it after a day at most!).

I agree it's discourteous to use an uncommon abbreviation without explanation. But IP3 is a very common abbreviation when discussing mixer or receiver performance, and it's reasonable to assume that anyone more than superficially involved in receiver or mixer design or application has at least heard the term. Or that they can at least do a simple google search. (It really doesn't take any more time than making an angry newgroup posting!) A google search of "IP3 mixers" brought about 2500 hits. I'm sure that if you read one or two of them, you'll get the idea.

Fahnestock clips work fine, and they're easy enough to find (e.g.
Mouser), and they even add a bit of heat-sinking. BTW, to connect
both plates in parallel, put a clip on each plate, line them up
together and run a connecting wire through the screw holes, then
solder the whole thing (quickly) and you'll have a perfectly-fitting
dual plate cap.

I seized on the word "delayed" and linked it to the inclusion of a longer time constant in the AGC to the RF stages of the DX-394 than the time constant in the AGC to the IF stages. The Handbook example actually says "As an option, the AGC to the RF amplifier is held off, or 'delayed', by the 0.6V forward drop of the diode so that the RF gain does not start to decrease until larger signals appear. This prevents a premature increase in the receiver noise figure. Also, a time constant of one or two seconds after this diode helps keep the RF gain steady for the short term."

I think 'delay' is a misnomer if what we have in effect is a higher threshold of signal strength for activation of RF AGC than for IF AGC. 'Two-step' AGC might be a better description. 'Delay' seems a more appropriate term for the way AGC is implemented in the DX-394. RF stage attack speed is slower (extra RC time constant probably on order of 100ms)

than that for the IF stage and is clearly 'delayed' in reaching steady state, no matter what the signal level change is, as long as the AGC is activated by the higher, later level. Release speed of the RF AGC is similarly slowed or 'delayed' relative to IF AGC, certainly not by the 1 or 2 seconds in the HB example.

Having removed the 'delay' capacitor, I have not noticed any deleterious effect. What should I be looking for? Would there be some advantage in revising the RF AGC to achieve a 2-step AGC?

Still looking for feedback on these targets.

Had one private reply that raised an interesting point about noise blanker operation and 'delayed' RF AGC:
"You might want to test out a system of this sort in the face of a significant amount of broadband impulse noise - e.g car-ignition noise or something like that.

If the attack is made too fast, then impulse noise at a rate of, say, 60-100 Hz would tend to force the RF AGC into its low-gain state, and this could allow weaker RF signals to be buried in the noise of the first-stage mixer.

Using a longer attack time constant will render the RF AGC a lot less vulnerable to the effects of impulse noise. You can then use a noise

blanker, located prior to the first IF AGC, to trim out this noise. As long as the first-stage mixer and the RF amp stage aren't forced into excessive intermodulation by the content of the impulse noise, I'd expect that this approach would give you the best set of behavioral tradeoffs."

for 40m band even an SBL1 may be found inadequate and the solution is
- as you say - a high-Q input selectivity using a 7040kHz ceramic
filter which passes 7,0-7.1MHz within -6dB bandwidth.

I've been told that my FT-902 with schottky ring mixer is worse than
FT-901 with DG-mosfet 1st mixer, but I have no idea what is the main
problem.
I tested a mosfet mixer on 136kHz and found it adequate in most
respects apart from IF leakage, and ended up with 74HC4066 mixer -
used more for reason of being curious about it than that it was really
needed, see http://home.online.no/~la8ak/L1.htm , but it couldn't be
used on 60MHz as the orignal request was for, it might work on 40M
with HEF4013 LO divider on +10VDC. Again you are fed with lot of crop
from persons who don't understand the difference between what is
optimum and what it the most expensive, so I expect somebody to telll
me the nonsense of using FST3125 instead of 74HC4066 without
understanding that the latter has almost 6dB higher IP3, and it is
more fun to use an inexpensive device in spite of having the house
filled up with lot of other better and expensive devices you won't
have time to use in a lifetime.

OK...I'll reset my time machine and do another 52 years in the business... :-) :-) :-)

>and for many purposes it is an advantage when the odd harmonic content
>is low

Outside of a step-recovery diode multiplier for an L-band sampler-locked oscillator worked on about 1974 (oscillator at about 1.6 GHz), I've not found much even harmonic content from a symmetric square wave.

Unsymmetric digital signals haven't been found to have much more even harmonic content than odd harmonit content when viewed on a spectrum analyzer...until the digital signal pulse width is VERY short compared to its repetition time. The SRD is able to get about as short as such pulses go and the duty cycle is in fractions of a percent. [also "avalanche diode" which I'm sure that someone will bring up sooner or later to start another argument...:-)]

The original question was about "practical multiplier stages." Those would range from doublers to quintuplers. Going much higher HAS been done but it takes VERY expensive lab instruments to prove them out, such as with an SRD "comb generator." Comb generators have all sorts of harmonics but trying to extract, say, the 21st without passing the 20th or 22nd harmonic requires a very fussy high-Q filter. Some of the things _possible_ are not quite in the homebrewer workshop category...or they take a LOT of time to complete.

I mentioned the passive diode doubler for the simple reason it IS simple when used with a distorted sinewave source (not a square wave). The effect of the two diodes in a "full-wave rectifier like" circuit creates an artificial 2nd harmonic by adding one sinusoid swing with the other, opposite-polarity sinusoid swing inverted by transformer action. Jim Pennell commented on that previously (and quite correctly). That makes for a broadband, non-fussy doubler circuit. Old thing and not a super whiz-bang state-of-the-art, hot-off-the-drawing-board wonder but it works. :-)

Heh heh heh, can't say I blame you for being a bit confused.

The "3rd Order" label is due to the mix products of F_a +/- 2F_b
with F_b being twice its original frequency. "Order" comes from
the constant multipliers, 1 for F_a and 2 for F_b so "1" + "2" equals
3 or the 3rd Order.

What happens is that the slope of the "3rd Order" mix product is
steeper than the normal F_a +/- F_b (order of 2) equation's power
slope. The "3rd Order Intercept Point" is where the two slopes
intersect.

It is much much easier to show this graphically than in words.

The reason for defining intermodulation distortion that way is in
that it is simpler and more accurate to test on both the production
line and in any test lab of a finished product. The old way had been
to just increase the input level and VERY carefully note the output
level, especially when the output level slope departed from a straight
line (indicating some compression, the start of intermodulation
distortion). That old system being very prone to instrument
calibration errors led to some arguments between makers and
buyers, not to mention non-standard notations of "1 db points" and
"3 db points" of distortion relative to input levels.

The Mini-Circuits website used to have some mention of the above
plus the Avantek website and, of course, Agilent when the T&M
division was the original Hewlett-Packard. You might find something
on a search for "3rd Order IP" on the 'net that will also have graphs.

>momentary overload.

According to terms used a half century ago in tube-type receivers,
"delayed AVC" (they used 'AVC' back then instead of 'AGC') just
meant that AGC action is delayed from taking effect until the signal
level rises above wide-open gain. Wasn't a time delay, but closer
to "hold off" voltage of some sort on the AGC control voltage action.

"Attack" and "decay" meant the time of response of the AGC, in
the same manner as audio-only control circuitry for broadcast
audio modulation input. "Attack" being the onset of a signal and
subsequent audio gain reduction time..."decay" being the release
time of any audio gain reduction control signal, that 'decaying' back
to original high-gain amplification.

I suspect that the original "delayed AVC" came about from two
reasons: First was that 'communications receivers' of olden times
usually tuned a rather wide band, usually 1:3 in frequency range
and the non-AGC gain varied by almost the same amount as a
result of tuned circuit impedance changes (tubes would amplify
almost entirely by only voltage changes when running Class A).
A hold-off on the AGC action handled the difference in overall gain
at the extremes of tuning.

Second, and I suspect the stronger reason, was that customers
could hear the front end noise in the speakers (with AGC held
totally off and gain wide open) and get the impression of a "really
hot receiver!" :-)

It's easy to get any kind of "delayed AGC" or hold-off on AGC
control with a DC bias on the detector.

As to the attack and decay times you specified, seems good to me. That can be set to suit the individual listener.

By the way, the topic of third order intercept point is covered very nicely in _Experimental Methods in RF Design_. As in its predecessor _Solid State Design for the Radio Amateur_ (Hayward and DeMaw), the authors point out that it's not always obvious whether the intercept is at a circuit's input or output, and consequently the importance of specifying which is meant. So in that book, you'll also find the more obscure but unambiguous abbreviations IIP3 and OIP3.

And pay special attention if this is input IP3 (the power of the test tones are measured at the input of the device) or output IP3 (power levels measured at device output).

This is especially important, since a typical active Gilbert cell mixer (1496, NE602) have some gain, while a typical diode ring mixer (SBL-1) have a 6-7 dB loss.

The circuit can be found in QST Nov 1992 (Recent Advances in Shortwave Receiver Design)! I t is unclear whether only two switches are used or if each switch is actually two in parallel. The biasing should be OK!

Hi,

I'm trying to track down the name for a certain type of oscillator
which I dimly recall seeing in an old book called Radio & Line
Transmission that I bought and lost over 3 decades ago.
In simple terms, it has a crystal in the base/emitter circuit and a
C/L tank for the resonant frequency of the crystal in the collector
circuit. In this way it can't flip into an overtone since it only has
gain at the crystal's fundamental. Anyone know the name for it?

Thanks,

p.

Heikki,
I dug this issue out of the archives and looked at the circuit. I'm not surprised that the performance is not real good. This circuit has no balance or switching symmetry. It is a simple half-wave switch which samples the IF at the BFO frequency. The output will have significant energy at the IF frequency as well as the BFO frequency, and these components might be overloading the audio amplifier.

I'd suggest something that has full-balance. You could modify the '4066 circuit to have this property if you could generate 2 opposite phases of the IF and drive them separately into the inputs of the two '4066's. If you set it up right, you will get very large dynamic range.

Alternatively, a traditional double balanced IC circuit such as an NE602 or even a diode DBM will work just fine as long as there is adequate selectivity in front of it to ensure that it is normally working with one IF input signal.

==========
Indeed a very nice handy (cordless) soldering iron I have used regularly since the mid 1980s
It is powered by 2 NiCad cells (total 2.4 V). and when not in use sits in a table top charger which is very primitive.
The charger is no more than a tiny transformer with an internal diode.
The problem is that keeping the iron in the powered charger all the time for readiness , there is no control and after some time the batteries get rather warm.
I now have modified the charger by removing the transformer ,fixing the unit on top of a separate plastic box inside which there is a 12 V transformer , small bridge rectifier , 1 electrolytic cap. ,a LM317 used as a constant current device , 2 resistors , 2 LEDs a few diodes and a DPDT front panel switch.

When not in use the switch is in trickle charge position (10 mA) with green LED ON
When the iron is in use the switch is put in normal charge position (approx 300 mA) with red LED ON

3 small diodes in series are always in circuit causing an approx 1.9 V voltage differential ,sufficient to light either LED.
This means that either LED is only ON when the iron is placed in its charger . Hence when the iron is placed in the charger and none of the LEDs are on ,there is a problem (bad charger contacts or blown fuse wire inside iron , the latter an unlikely event since modifying the charger)

I mainly use the fine tip Wahl Clipper Corp. nr 7566 costing US$ 6.75

Over the years I have replaced the batteries twice (before modifying the charger a few months ago)

Note : The fine tip is very handy when working with SMD components.

Mentioning a certain voltage level doesn't really make so much sense
when you don't know what the rest of detector stages looks like. Drake
2-B has 5Vpp from 6BA6, and R-4C somewhat less, but not too important.
This is only a reference which may not apply to any other receiver
because it is another AGC amplifier which also amplifies IF to the AM
detector for 2-B, and product detector fed via a voltage divider. For
R-4C everything is totally different, and the 4-5Vpp level seems more
chosen for economical reasons. Another English LF communication
receiver I checked had 80-100V pp IF output. The level to choose
depends on good AGC characteristic, and usually the IF level should be
certain level above the background noise, possibly 10-20dB for good
operation. Some receivers have not particularly good AGC, Atlas 210X
is one, and my Yaesu FT-902 is another, even worse is FT101B because
carrier oscillator leaks into the IF and AGC threshold must be set
10dB above the level you would want it to to start, simply because it
can't operate properly below it.
It was a surprise to learn that the Lorenz 6P203 receiver operated
nicely on SSB when BFO level was increased, in spite that it has only
6AV6 detectors, but IF is split, and it has two different 6BA6's with
different diode detectors, one for AM/CW/SSB and one for AGC.
http://home.online.no/~la8ak/b71.htm
Siemens Rainbow receiver also had some improper connection between
product detector and BFO, and could detect SSB well when this was
corrected http://home.online.no/~la8ak/b72.htm
Heathkit SB300/301 have bad AGC, but may be easily improved a lot by
using 1N4148 AGC detector diodes (voltage doubler), simply because the
original diodes have too much capacitance and do not rectify properly.
I did some experiments using Drake 2-C type and R-4B type AGC
detectors in my Kenwood TS-500, later in 2-B, and could set the
detector output variation from AGC threshold to as little as 1dB, but
it seem no real point since the subjective sound seem best with at

least 6dB variation, but wasn't too important if it was kept as
original 10dB for 2-B, it is only important when you have a lot of
advanced measuring equipment in the shack, but not at all for the
radio operator.

One thing bugs me about building oscillators and that's the
possibility that they may not start in the first place, or else start
fine then somewhere down the line just flip into an overtone or
sub-harmonic for no apparent reason. If only one could physically prod
the circuit around to induce instability but of course that's unlikely
to show up any potential problem. What's needed is some method of
instigating instability to try to show up any latent tendency for any
particular osc to go tits-up and I can only think of one practical way
of precipitating it: varying the power supply voltage.
If one can vary the supply over a fairly wide range and the oscillator
only responds by very small changes in output frequency and doesn't
jerk into another frequency/output mode altogether, is this a
sufficient test on its own of that oscillator's likely stability in
the field?

Dip it in ferric chloride for a couple of seconds then rinse with water, it will then take paint perfectly. DO NOT LEAVE IT IN TOO LONG AND TAKE CARE. suggest doing this in an open space as it will react much faster than copper.

Why don't you think the crystal goes low impedance at it's odd harmonics? If you'll design the circuit properly, it will give no trouble with overtone operation. Don't remember ever having any problems selecting one to operate on the fundamental, usually, it's selecting between 5th and 7th overtone or 7th and 9th that gets a little sticky.

I don't know, but if you know the frequency of the overtones, try
injecting that frequency. Use a really strong signal so that it
dominates, then switch it off and see if your oscillator snaps back
to the correct frequency.

A universal series resonant circuit "Butler?" meets most of your
criteria. I dont like these names myself. Collector to +ve supply via
tank LC with the C = 2 C in series the base decoupled to ground with a
potential divider to set base bias and a low value (220R?) in the
emitter to ground.
The crystal goes from the junction of the 2 tapped capacitors and the
emitter. The 2 Cs are arranged to lower the o/p impedance from the
collector tank i.e. the C nearest the collector would be 100pF and the C
to the +ve supply 330pF. With the LC arranged to resonate at the crystal
frequency.
The beauty of the circuit is that the crystal can be replaced by a 50R
resistor and the circuit L and C tweaked to oscillate at the crystal
freq. Can be used to select overtone or fundamental.

You're probably thinking of the oscillator that Marv Frerking
called a "grounded-base oscillator". I have seen it called other
names as well. Basically, what you do is first build an LC
(ie no xtal) Colpitts oscillator and tune it to the crystal frequency
you want to eventually use. Then insert a resistor of a few
dozen ohms in series with the emitter. Now, readjust the feedback
capacitors on the oscillator to get it to oscillate OK with the resistor.
Finally, replace the resistor with a series resonant crystal.
It will be forced to oscillate at the frequency of the original LC
oscillator, since there is no gain anywhere else. Thus you can
design for either the fundamental or a specific harmonic and like
you say it can't flip to a different overtone. For more details,
read one of Frerking's books.

Alternatively, take a look at the Butler design by John Stephensen in November/December 1999 QEX. He explains clearly why folks ever had problems with Butlers and better yet, how to cure them. I've used this circuit (without the Varactor tuning) on 9th overtone oscillators using hound dog crystals.

Thanks Spehro. Delightful! I wondered what it had to do with things until down the page a bit.

Sorry for the lack of definition, I was referring to crystals not specifically treated to enhance overtone operation. When a manufacturer makes a crystal for overtone use, he/she treats it to suppress spurious responses close by the desired overtone so the crystal "likes" to operate properly. An untreated crystal often will have those responses and oscillate on one or more of them instead of the desired frequency unless the feedback and tuned circuit are carefully managed to ignore them. The higher impedance of Stephensens schematic make that a bit easier to do.

Yes. This area is all about limit cycles, attracters, and such like, in
non-linear equations.

There is no general solution to non-linear equations. One can only use
experience and brute force by trying the usual suspects.

Huh? Try a 1/3 -- 2/3 ratio. NO third harmonic (or sixth or ninth, etc); second is the greatest amplitude harmonic at fully 1/2 the fundamental amplitude. Fourth is larger than the fifth. For a symmetric square wave, there's no second and the third is only 1/3 the amplitude of the fundamental. Easy to verify with a spectrum analyzer or through a Fourier series. As the pulse width goes to zero, the fundamental and all harmonics go to equal amplitudes. At 5% pulse width, for example, the harmonic amplitudes decrease monotonically as harmonic number increases, out to the twentieth, which is a null, but even the 12th is fully 50% of the fundamental.

This is useful info if you're trying to design a simple amplifier-type doubler; adjusting the conduction angle to approximately 1/3 will give you lots of second but little third, making it easier to filter the output. But if you weren't thinking about it and tried to make a tripler, and accidentally made your conduction angle 1/3, you might wonder why you were having so much trouble getting good tripler efficiency.

Cheers,
Tom

Normally...but it may not satisfy everyone in here. :-)

What should be done in oscillator design is to make the minimum gain through the feedback path - under all environment conditions, including variation in supply rails (filament voltage if tubes) and even component tolerances and tolerance changes - above unity by a fraction. Then the opposite environment conditions should be examined and the gain through the feedback path analyzed to see if it exceeds unity to much. Too much gain might overdrive a quartz crystal unit or generate harmonic garbage or whatever else might be a no-no.

Once the above is satisfied, the prototype is then subjected to actual environment changes, again everything from temperature, shock, vibration, supply voltage, etc., etc., while measuring the oscillation frequency changes with each environment condition. To go really deep into that, one might get a number of active devices with varying tested specifications and try them...but that would only be for large production runs of the same thing.

If the frequency stays within the desired limits, it passes! Yay! :-)

In too much hobby work, someone grabs a schematic from some publication and copies it, but usually with some parts changes ("for convenience") and hopes it will work. Sometimes it does. Sometimes not. :-)

Oscillators are actually a rather complex subject and take time to get working within all the desired specifications. Before SPICE and the ability to model ALL the various things in a circuit, all analysis had to be done open-loop. The loop (for feedback) could only be closed on the bench. That work was a real #$%^&!!!!

The best text I have on oscillators is a rare, little-known NTIS-distribution contract report, AD 460 377, "Quartz Crystal Oscillator Circuits Design Handbook," prepared by D. Firth at Magnavox Company, Fort Wayne, Indiana, under contract to U.S. Army Electronics Command, Fort Monmouth. It was obtained mail-order

in 1985 from the National Technical Information Service (NTIS) from
the U.S. Department of Commerce. Cost $8.20 for 478 pp, Xeroxed
on 8 1/2 x 11 inch paper. Original contract completion date is given
as 15 March 1965. [yes, transistors were around back then...:-)]

"D. Firth" (name sounds very familiar) covered the whole gamut of
oscillator frequencies from 1 KHz (!) on up to 200 MHz, showed the
gain-impedance analysis of the feedback loop, and working units
done for actual environmental test and the test results which
included variations in not only supply voltage but also component
tolerances of each test unit! Marvelously complete report...can be
an example of how-to-do-it for anyone, including hobbyists who are
very fussy about their oscillator circuits, especially quartz crystals.
It's also a good tutorial that goes deep into circuit theory for
oscillators.

I'm NOT saying everyone ought to get that publication. There's lots
of good information around and a lot of that free (for quartz oscillators)
at the various quartz crystal makers' sites. Basic information on
oscillators, types, etc., is in lots of places and publications. The
final word on oscillator performance is its frequency stability over a
hobbyist-designated total environment.

Accuracy of a frequency measuring device to measure that oscillator
frequency is quite another thing. :-)

Thank you, Tom...but I've done the "SineX over X" thing a few times already and looked at a lot of spectral displays. Even wrote a computer program or three to determine the harmonic content of various arbitrary-shaped defined waveforms (two for corporate use, one in a shareware/freeware package).

The first null of ALL harmonics occurs at frequencies at the inverse of the repetition time of the waveform. That turns out to be fairly true for any waveform, not just a pulse. Trouble is, the harmonic content NOT at the major null increments varies considerably in actual practice since the source of RF being multiplied varies in shape in actual practice.

Discussing harmonic content is so much bafflegab without first defining the source's waveform shape...even if to coarse levels of square wave versus sinusoid versus pulse or whatever.

The kickoff message to this thread started with "square wave" and all I did was further refine that to symmetical square wave. You aren't going to tell me there's a lot of even harmonic energy in a symmetric square wave because I can set it up on the bench and demonstrate it doesn't. Practical test versus theoretical and results match.

I once managed to phase-lock a pulse generator in order to key
on a signal generator output for exactly ONE RF cycle (35 db on-
off ratio). Interesting broad spectral content, way wide almost
like an SRD output. Impractical, of course, was to satisfy a
couple of others arguing the whichness or the what one day. :-)

Well, I'm not wondering at all since I haven't built any vacuum tube
or FET active multipliers, just the bipolar transistor types that don't
quite fit into the old "conduction angle" simple rules.

Correction: Built a tube crystal oscillator (6AK6) that doubled or
tripled (as desired by tuning) to be the LO for a 6BE6 pentagrid
running at external LO injection. Behaved like a fundamental
crystal oscillator that doubled or trippled in the plate. That was
around 1960 and didn't have the tools to check waveforms on my
lunch hours. :-) Just played with it until it worked...and had
enough LO injection to run the pentagrid at good conversion
transconductance.

Why bother to use frequency multiplier stages NOW when PLLs
and DDSs can have oscillators at their fundamental and those can
be divided down with available parts to a low, stable lock frequency?
It's fine for restoring antiques to use lots of multipliers, but, let's
face it, those can be a pain in the expletive deleted to recreate now.
Others' mileage varies, of course.

I mentioned a simple two-diode "full-wave" doubler because it is an
easy thing to implement and is broadband to start with...no fussing
with tuned-circuit impedances at the start to make it work with a
non-square source waveform. It may not be as efficient as some
would like but it is easy to do compared to direct active doublers.

This pdf schematic looks very similar, except for the crystal and emitter part, to a circuit described in "Experimental Methods in RF Design" (p4.13).

The circuit is described as "worth building.....to observe first hand just what a noisy oscillator will sound like in a receiver".

Earlier in the same chapter it appears in figure 4.13 as a type of negative resistance one port oscillator.

I can only assume that the changes and crystal (in the circuit shown in the pdf) solve the problem of the "noisy" LC only configuration.

I mention it as I built it up last night and took it into work today in order to have a look at the output on a spectrum analyser. Output was quite low at -27dBm. Sadly the HP kit couldn't measure phase noise directly, and I didn't have a good crystal oscillator to check it against.

We were uncertain regarding the configuration too, but my colleague worked out that it had severe voltage limiting features and predicted the output swing quite accurately before it was measured on a scope.

Last night I tried it with a number of inductors from the junk box and it oscillated quite readily from 114MHz down to 5MHz. I quite like the use of a non tapped L and only a single C. Shame about the phase noise :-(.

regards...

Just did an interesting little 'speriment. Standard diode "full wave rectifier" frequency doubler. Transformer is 16 trifilar turns on an FT50-43 core (should be a bit more than 50uH per section). One of the triplet is the primary, and the other two are connected as a center-tapped secondary. The diodes are 1N4007 -- yep, the 1kV mains-freq rectifiers. Excitation comes from an HP3326, set to square wave output, source impedance 50 ohms. 50 ohm load impedance on the doubler output (input to spectrum analyzer; DC coupled load). HP3326 square wave risetime is about 10 nanoseconds, I believe. Excite at 0.5MHz, +/-2V (4Vp-p) Output waveform observed on a fast scope is frequency-doubled, close to 50% duty cycle, with fast falling edges and slow (200nsec) rising edges. Amplitude about 2Vp-p. Strong spectral output on all even harmonics; all odds suppressed about 20dB from the low evens, and I'm sure would be much lower with better matching of the diodes.

Explanation left as an exercise for the reader, but should be obvious from previous discussion here. I'd guess 1N4148-type diodes would behave similarly for an input around 100MHz.

Cheers,
Tom

Joe, I'd gladly use the Analog Devices DDS chips if they offered them in something other than a SadoMasochistic Device (SMD) package. It's a darn shame they can't make a limited run (say 10k) of some of these chips in a PDIP package for hams and other r.f. experimenters.

If they put the AD9835 in a PDIP and sold it for about $10.00 (the TSSOP packaged version sells for about $6, I think) , I'd buy a dozen for various projects, but in the tiny SMD package they're nothing but useless to me.

I'm new to the newsgroup and am sure that this is not the first gripe about SMD's, but I refuse to use them - not because I can't (at least not yet), but because I don't want to endure the angst.

Sounds like a good opportunity for an enterprising ham - fab up a
bunch of adapter boards (or buy 'em premade - I think Ares has
something like this), solder down the SMD parts, and sell the
resulting PDIP-compatible boards to interested homebrewers.

Thank you everyone!

I haven't tried "Meter", but "Dial" already made me the proud owner of a nicely printed 0-100 linear scale.

Question: I had to do a screen capture and print via IrfanView, as the Radius setting had no effect on the printed size. Did I do something wrong?

(However, using the screen capture, the result is excellent!)

Re. log scale: don't you get any serious problems with fine rendering / printing? My PC/Video/printer work very well with Meter + IrfanView, but I can't get anything decent out of Excel/Open Office, as both approximate fine divisions too roughly for any practical use, even when doing HUGE pie charts.

Thanks again, sooner or later I'll post pics of the new rig.

It will (should) be a broad tuning-range HF regen with a highly repositionable, crystal referenced bandspread (either one generic 0-100 linear scale with tuning graph book, or perhaps a series of slide-in tuning cards, both so cutely retro!) plus switchable wide/phone/CW audio bandpass filtering, and a few other tricks.

Also, by the way, do you know of anyone using a film scale + lamp + lens to PROJECT the tuning scale in a homemade device? This would be sooo cooool! I'd even be tempted to print in the names of a selection of broadcasters, coastal stations, nets, QPR windows, USN fax, GCSS, whatever....

oscillate
>on one or more of them instead of the desired frequency unless the
feedback
>and tuned circuit are carefully managed to ignore them. The higher
>impedance of Stephensens schematic make that a bit easier to do.>

The special techniques were as follows:
Optimise the plating thickness for the overtone and also the electrode
diameter.
Shear mode crystals have a controlled relationship between the resonant
frequency under the electrode and the frequency away from the
electroded region.

Also higher overtones are better polished and more sensitive to
parallelism.

Overtones pull less approx pulling of fundimental/overtone number
squared.

> Len Anderson
> retired (from regular hours) electronic engineer person

Earned a good living designing (fairly) reliable crystal oscillators for
many years.
The enemy is excess gain or not enough gain.
For non series res designs like Coulpitts/Pierce I always establish a
negative resistance across the crystal that is 3X the max specified
crystal ESR.
See Telequarz app note now Corning)
Or read my orig? Wireless World paper (1968:))

For overtones use the resistor substitute method (one or two transistor
Butler) and ensure again that the osc will go with 3X the ESR.
Note the phase shift osc can be converted to series by adding sufficient
L in series with the crystal to establish zero phase.

Higher overtone may need the crystal C0 tuning out.

Chip,
I totally agree with you about the difficulty in handling fine-pitch SMD parts. It's a sign of the times.

FYI, check out the DDS Daughterboard at www.njqrp.org. This is a DDS application board kit with on-board clock oscillator (you could run it from an external oscillator if you wish). There's also a link to a service that will solder your DDS chip to your bare board for $6 in single quantities.

In the case of RF devices like DDS's and high-performance microprocessors (you think 1GHz isn't RF?) the surface mount package significantly enhances performance. I haven't found them to be that bad to work with; you just need good eyes and a steady hand.

While blasts from the past, let me remind you of the CD4059 and the much faster 74HC/HCT4059. The 74-series parts guarantee operation on inputs as high as 20 MHz. "typically" as high as 50 MHz. These will divide by any binary value from 3 to 2^16 or even as high as 21327 with some gaps.

The division ratio is set by 16 external pins plus some configuration pins (24-pin DIP package).

The rub is that the part is very rare these days. I suppose discontinued.

Yes Tim, I agree. Unfortunately, the physics of RF favors "small" and "compact". This is the price we pay for such high performance. It's not yet to the point where it's a 'show stopper' for experimenters, but you have to be increasingly resourceful and persistent. Many have dropped out of hombrewing at a time when the possibilities are most exciting, merely because they can't or won't adapt to the new packaging technologies and the need to learn a little about firmware programming in order to make the new generation of parts work. It's not that they "can't" learn, it's mostly that they "won't" learn.

Martin:

It works more along the lines of a regular soldering iron in that it
is intended to be turned on and then left on during a single soldering
session. But it does have a rapid heat up time and may be able to be used
in the way that you are speaking.

The device is a Metcal soldering station. The tip will go from
cold to hot and useable in about five seconds. The tip has the temperature
regulator built into it and the tip can be easily changed to different
types and temperatures that would be most suitable for the particular job.

Maybe you could use it with a foot switch to turn it on much as you
turn the sodering gun on now. The benefits would be to have a much lighter
hand piece. Easily changed tips. And more stable temperature at the tip.

Good luck and I hope this helps.

Found a source for 7360 and it is some interest among my friends for
using this tube in HF receivers, particularly for 80 and 40m
It was mentioned an article by W2PUL(?) in QST using a high current
twin triode as RF amplifier.
Have seen the SSR-1 rx schematics. Is some more notes available on
some sites for a modern version of receiver using these devices? I
suspect some parts of the receiver could be improved over the practice
used in the 60's
Any suggestions?

The radius should affect the printed result. *HOWEVER* - the radius in the Windows version is in pixels. On your printer, pixels are usually pretty small these days, so you need to make the dial absolutely huge on the screen to print reasonably.

Most commonly printers are 300 dpi (although some newer ones are a lot higher) so a radius setting of 150 would give you a 1 inch diameter dial.

Thanks for the interesting examples, Jan-Martin. The quote was from the 2004 ARRL HB page 17.23 in reference to a schematic/block diagram of a "typical superhet receiver with AGC applied to multiple stages of RF and IF". The RS DX-394 bears some resemblance to this with a resistor in place of the "Delay Diode". It beats me how the AGC in this HB example actually controls the RF gain - the diode appears to block control. A second one in parallel in the opposite direction seems to me to be needed.

The latest article I can think of seeing in print was February 1972.
I may have the date wrong. It was by one of the QST staff members
but not Doug DeMaw; I want to say Doug Blakeslee.

It was a 3.5MHz receiver with a 455KHz design, hardly cutting edge.
But it was intended for strong signal handling, so he used a tube
in the RF stage that had higher current handling. He half jokingly
suggested using an 807 in that stage.

A lot of those articles using the 7360 used no RF stage, which is
why you often saw a signal frequency Q-multiplier, to aid in image
recection. Of course, by the time the 7360 was put to use, HF range
IF filters were available so many of the receivers used an IF in
the 5 or 9MHz range.

Ray Moore had some articles in Ham Radio in 1972 and 1973 about
receiver design, and the introductory piece covered mixers including
the 7360, and then he had a "construction" article on a fancy AM
BCB receiver, that used a 7360.

Maybe some work was done with the mixer after that, but it pretty much
faded from view from that point on.

A couple, With Colin Horrabin's "H" mode mixer and the later switch mode
mixers available for well under a buck, the mixer has been removed from
being the concern it once was in receiver design. Since that topology, and
the 4066/312X/500X solid state mixers yield better linearity than the
following filters do, why return to the 7360? It was a fine mixer in it's
day. That day is LONG past. Try operating a 7360 in any close proximity to a
flourescent ballast. It will quickly disallusion you as to it's relative
worth except as a curiosity. Vacuum tube receiver technology and modern is
an oxymoron.

I have an old Heath SG-6 signal generator. It uses two triodes.
I'd like to convert it to solid state. The switched coils, varible cap
and dial mechanism are very nice. Any suggestions on what kind of
oscillator circuit I should use? I imagine the difficult part will
be coming up with a feedback circuit that will cover the 160 kHz to 50 Mhz.
Any ideas? Has anyone seen any articles on this kind of conversion?
By going solid state and adding a few buffer stages I'm hoping I could make
this thing a lot more stable. 73 Bill M0HBR CU2JL N2CQR

Re-mounting an SMD onto a DIP header guarantees minimum ground-lead lengths of about a quarter-inch, so watch out for some "interesting" changes in performance.

>I haven't found them to be that bad to work with; you just need good
>eyes and a steady hand.
>
I don't have notably good eyes or hand co-ordination, but have done plenty of SMD work using an extra pair of strong reading glasses (on top of my normal pair) and a Weller TCP iron with the finest-pointed conical tip.

It's remarkable how your hands become much steadier and more controlable when viewed under magnification. The other thing is to rest your elbow or forearm on the bench, so you only have to move your wrist and hand. Oh yes, and lay off the coffee and Coke for several hours beforehand!

Given those aids, anyone who doesn't have a clinical condition affecting hand co-ordination should give SMD a try. (Note: "I don't want to" is not a clinical condition :-)

Other essentials:
* a good work light
* thin silver-loaded solder (20g maximum)
* a flux pen or a supply of liquid flux
* thin fluxed desolder braid (1/8in maximum)
* a good pair of tweezers, that won't cross over and flip the SMD to who-knows-where
* a clean workspace, because you *will* drop things

With only that equipment, I've mounted AD DDS chips (and much else) on a board and they worked first time.

SMD work *is* do-able... so just do it!

You should be able to replace the triodes with FETs, this was done
occasionally when FETs first became available. You'll probably need to
fiddle with some of the component values. Don't forget to reduce the HT
voltage. 8-)

Interesting. This is the type I've decided to build as the basis for
my next sweep generator attempt, since it's claimed the config is more
amenable to being pulled than most others (although I won't be
attempting to pull it anything like as much as my first abortive
attempt using a Cmos-based inverter). Do you find it's a reliable and
stable design, Jim? I assume if it wasn't you wouldn't still be using
it!

A couple of decades ago (shite, time flies) I purchased a Marconi TF995A/5 sig gen. In common with many gens of that era, these suffered warm-up drift and the occasional wander after that.

Well, this one didn't. I'm not saying it didn't drift, but nothing like its peers, and it warmed up quicker. Explanation? The previous owner had fed all the fils off a regulated 5V DC add-on. Might be worth a quick try to see if that approach gives you enough improvement, before you get into serious redesign.

The above proves that a basic bottleneck in humans is the tendency to
resist change.
Fortunately there are also many (humans) who see change as a challenge.
I prefer to belong to the latter category and will shortly 'get into SMD' by
building a DDS VFO
(ref KG6CYN) ,be it that I am currently doing some 'home training' by
messing about with SMD components from discarded consumer electronics.
After all homebrewing electronics is and remains a great hobby.

Great attitude Frank!

Those of us who have been around for a good number of years can remember the old farts who refused to adapt to SSB when it began to displace AM, then refused to learn about transistors when they began to displace tubes, then refused to learn about microcontrollers when virtually every new product had at least one in it, and now refuse to learn how to use SMD's. There's much more change to come that will dramatically change this hobby, including the DSP revolution, TCP/IP networking, and exciting digital modes. Many hams will become artifacts because they lament "I won't or I can't". Others will boldly say "I can" and "I will", and they will be the ones who are having the time of their lives exploring new technologies while the others just constantly relive their past.

No kidding!

During the development of the Phoenix Missile Solid State Transmitter, which used 16 IMPATT diodes in a cavity power combiner, we were serializing every diode.

The state of the art in diode manufacturing was such that getting 16 matched devices was almost impossible, so we tested hundreds and then picked those that most closely matched. These were a microwave pill package with a 3-48 screw and a flange about 2mm in diameter. We scribed about a 10 digit serial number right into the gold on the flange.

I was good for about 30 diodes each morning until the coffee and shakes set it.

As Leon said, you should be able to change the triode to an FET, with
minimal change. In other words, leave the oscillator as it is, and
merely change biasing.

I once took a Collins PTO, bought at a hamfest for $2.50, took out the
tube and wired in an FET across the tube socket. Obviously, I reduced
the "B+" to around 12V or so. I can't remember if I even had to change
the plate resistor (there might not have been one, but instead an RFC).

My sincere apologies. I thought you had posted something about
relatively little even-order harmonics unless the pulse width is very
short. As you've done the calcs and know that in a 1/3-2/3 rectangle
wave, there's well over two times the energy in the second harmonic as
in all the odds put together, I'm obviously mistaken about what that
previous posting said.

Cheers,
Tom

Your solid state devices will either be really light-weight or will have
significantly higher capacitances than the tubes, so it would be very
difficult to get your oscillator to track.

I've got an RF-1 which I've contemplated upgrading. Before I went to solid
state I'd give the filaments a regulated supply (like budgie's post) _and_
put in a regulated plate supply. A solid-state wideband buffer would
probably be a quite good idea; a 0-50MHz broad-band amp into 50 ohms should
be fairly easy.

Certainly. I've just finished roughing out the block diagram, actually
and will try to post it later for some constructive criticism. It's
basically just to sweep a half-meg segment in the 40Mhz band for the
purpose of testing filters to improve rx selectivity in R/C
applications..

About a month ago, there was a gentleman in here deciding on what to give his son to teach him electronics, construction, etc. A kit of some sort? There was a long thread on this. The pros and cons, ease of construction, practices, keeping him interested and so on.

I'm curious of the final decision made and how the young man is doing? I can't recall hearing of any progress on him, unless I missed it. What did/will he end up building - how is he coming along with his "studies"? I do wish him good luck. MNS

I did quite a bit of shopping, concentrating on kits that use the SA602. I found out that it had to be a "Neophyte", because that's the article that lit the fire. It was in the ARRL's QRP Compendium -- I'm not sure of the title (it's a long walk from here), but it's a collection of article reprints of various QRP projects.

I bought an "Improved Neophyte" kit from Dan's Small Parts and Kits (http://www.danssmallpartsandkits.net/). This kit has the FAR circuit board, a reprint of the "Improved Neophyte" article from the Spring '94 HamBrew Magazine, and "all" the parts. The circuit seems to be solid, but I have to give the kit a "C" -- whoever kitted it made some counting errors; there were a couple of caps and resistors missing, and the construction article is missing the last page. It's working fine for us because I have a well-stocked shop and I've scratch-built receivers before, but a beginner would have trouble without help.

He learned to solder right off, but the kit building has been stalled for a couple of weeks because he has to be caught up on homework before he can work on it. We should have probably stuck with a straight "Neophyte", or jumpered around the "improved" parts of the circuit and gotten audio fast and full performance later, but I didn't put my foot down.

I expect that with pestering from dad we'll get things done some rainy day, and then I can steal it from him.

Well, it sounds like you at least got things going. Heathkits as good as they were, Eico's too - have had their share of problems, so I guess you can't complain. I hope all goes well for him. You're right, you got to keep after him and with some of the "problems" it does pay to have someone around who knows. One step off the beaten path to create a disappointment for him could spell disaster. Hope all continues well. MNS.

In article <BC601BA8.82B%outhouse@midcoast.com>,
U <outhouse@midcoast.com> wrote:

>So which chargers can I leave permanently attached to a battery?

What you want is something called a "float charger". It provides a carefully-regulated charging voltage (typically in the 13.5 - 13.8 volt range), with a current limiter.

>The word 'trickle charger' or 'shore power' comes to mind.

A trickle charger may, or may not regulate the charging voltage carefully enough to allow it to be hooked up on a semi-permanent basis.

If the voltage is too low, the battery may not maintain a good charge state, and may not recharge if you run it down partway.

If the voltage is too high, the battery will begin "gassing" - the high voltage breaks down the water in the electrolyte into hydrogen and oxygen gasses. If you don't replace the lost water (using distilled or demineralized water) periodically, the electrolyte level will fall below the top of the plates, and you'll lose charge capacity and may very well damage the battery permanently.

> How is that
>different from my old Sears charger which does me good for many years
>already (but I unhook it after a day at most!).

Standard battery chargers are often of a dual-voltage variety. They fast-charge the battery at a high voltage (around 14.4 volts) until it's mostly charged, and then switch to a lower trickle-charge voltage (13.8 or so) to finish the charging without excessive loss of electrolyte.

Unless they're designed for long-term float charging use (careful voltage regulation, with some amount of temperature-based adjustment of the float voltage), leaving a charger of this sort hooked up on a long-term basis can still result in some loss of electrolyte.

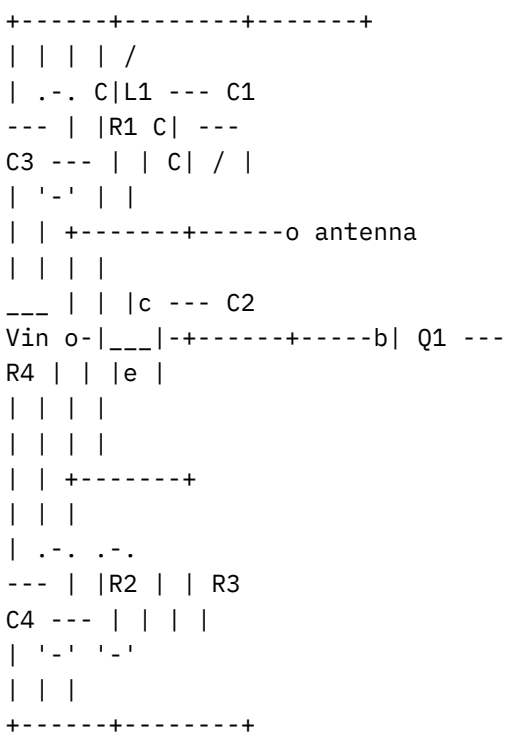
Why not use a VCO built from an LC oscillator? Its really easy to build one
with a single transistor that sweeps your band.

I built a simple one that looked like this:



Q1 = 2N3904

L1 = 0.5uH
C1 = 20pF variable from 10pF to 80pF
C2 = 4.7pF
C3 = .22uF
C4 = 1uF
R1 = 47k
R2 = 10k
R3 = 1k
R4 = 100

created by Andy's ASCII-Circuit v1.24.140803 Beta www.tech-chat.de

I was able to sweep the band from 40MHz to 42MHz by first adjusting C1, then changing Vin (with a pot) to vary the output frequency. I built it on a solderless breadboard (!), and had no problems getting it to work. With your newfound PCB skills, should be a snap to get something like this working. I tested it by counting waveforms on my oscilloscope, so your mileage may vary.

The resonant frequency is near

f0 = 1/2.pi.sqrt(L1Ct)

where Ct = C1 + C2||Cbe + Ca + Ccb

Cbe is the capacitance between base and emitter of Q1, which is varied with base voltage; Ccb is the 'fixed' capacitance between emitter and base of Q1; and, Ca is the capacitance of the wire antenna. I'm unsure about how to calculate the power output of the thing, but I'm guessing its tiny. I was able to sweep the FM band (using a 0.1uH inductor) pretty reliably, and it knocked out radios in other parts of my house when I swept past them.

The Q of the inductor should be as good as you can make. You can buy highQ inductors. At this value, an aircore is probably pretty good. Otherwise, your resonator won't stay on frequency. It'll drift with temperature, and probably the phase of the moon, as well.

Regards,
Bob Monsen

?

The HC4066 is OK(ish) to about 10megs.
A dual gate fet (eg 40673) -with care- should be able give out roughly the
same, or a little more voltage than what is coming in. With a diode ring
expect to pick up (say) only 40mV of an incoming 100mV.
[Easiest / most reliable]: use a "Bus Switch" such as the FST3125, toggled
by 74AC type logic; handle the A.C. signals by couple of video op-amps).
('Output' signal looks like what you see in a text book).

Jan-Martin,

I think the issue is that it is NOT a time delay, but a signal level
delay. The AGC does not begin to reduce receiver gain until the signal
reaches some defined LEVEL.

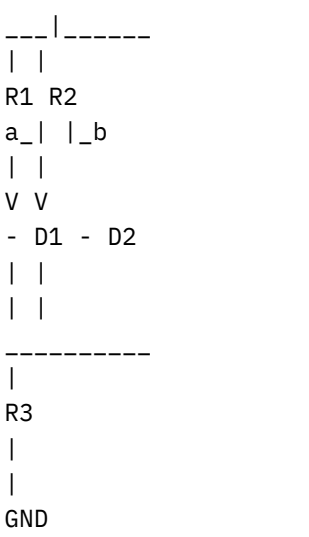
Tom,

I don't have the circuit, but have two diodes pointing down. Resistors
on both anodes to +V. Common cathodes with resistor to GND.



Changing the voltage at point "b" will cause "a" to also change. Another
way to look at it is that you steal different amounts of current away from

D1. Go too low at "b" and "a" won't change any more. It stops. However, go higher on "b" and "a" keeps going up. It is a limiter.

>probably be a quite good idea; a 0-50MHz broad-band amp into 50 ohms should
>be fairly easy.

Going to all-regulated supplies for a vacuum tube thing turns out to be rather easy. I've just finished breadboarding that for a 1960s era HF SWBC receiver to improve its frequency stability. Tube oscillators need a stable "B+" or plate supply that, in older days, was enabled by gas shunt regulators (OA2 or OB2, for example). Heater voltage variation is less of an effect on frequency stability but such does occur when the AC primary voltage varies to the extremes of its +/- 10% possible range.

On checking the HV supply of this little receiver, the OB2 strike voltage had increased beyond manufacturer's spec so it did not always strike and start regulating with power-on. The lone OB2 in spares, also 40 years old, was just the opposite, striking below spec. That prompted looking into a series regulator for the whole B+ using an ST (Fairchild also makes them) TIP47 series pass NPN with a 250 V breakdown and a 2N3440 250 V NPN as the error amplifier. Not a problem to have it regulate everything at +120 VDC plate supply, using only half of the original filter capacitor quad.

Regulating the filaments just barely works with a conventional 7812 positive IC regulator. My version is a combo series-parallel string of 6.3 and 12.6 V nominal filaments, the whole taking 0.6 A. With less than 10% ripple on full-wave rectification and 12.6 VAC RMS nominal, the 2.0 V minimum of series drop necessary is maintained even at 105 VAC primary transformer input. The filament voltage is maintained constant at 12.1 VDC within 1 percent at all conditions of AC primary voltage. To get a regulated minus, a 7912 (if it can be found) will do with rectifier and capacitor polarity reversed, handy for biasing other circuits with a negative voltage.

With a 6.3 V filament arrangement, that would be on the hairy edge of regulating at -10% AC line voltage. Filter capacitor needs to be high enough for only 5% ripple and rectifier diodes can't be much more

than 0.7 V forward drop to fit the minimum 7806 regulator 2 V head-room. Note: The original AC filament voltage was made within certain (seldom specified) limits; if that is on the low side also, the 7806 may poop out during droops in ripple voltage. 7906s were originally made in the series for negative voltage regulation, also good for providing a minus bias voltage. Tube filaments for indirectly-heated cathodes don't care about DC polarity. Slightly-lower than nominal voltage will improve heater life.

Higher voltage NPNs for series-pass applications are getting scarce. So are higher voltage zeners. TIP48 has slightly higher breakdown than TIP47, can work for higher B+ values although there's a need to check voltages for +10% AC line conditions rather than -10%. Exceeding breakdown voltage can be catastrophic to the transistor junction in just a single AC cycle.

> http://planeta.clix.pt/n2cqr

Hi Bill,

I'm in the process of doing something similar. I have (had) an old "University" RF oscillator, 6 ranges, covers 100kHz-130MHz. Based on a dual triode (oscillator and buffer) and a pentode for audio oscillator for modulation. This thing looked cheap(ish) and didn't work very well, would start and stop at various frequency settings. So I stripped it and decided to keep the tuning cap, range switch, and tuning coils.

Rebuilt it with a JFET (J310) but had to change the circuit. Coils are centre tapped and fed the supply voltage, so the Anode current flowed through the coil. When the FET was placed into the circuit this overdrove the gate and oscillation was erratic and unstable. Supplying through a resistor improved things quite a bit.

Problem I have now is with the low frequency ranges. The coils for this are large (they are air cored with a tuning slug?) so are high resistance as they have lots of wire. I may try to increase gain to compensate or else replace with a toroid.

As someone else mentioned, I haven't checked tracking so I don't know how well the tuning dial will match the frequency.

James.

Don't know how much power is involved and the average duration of an outage
, but the simplest way to keep power during brownouts is to use a
UPS=Uninterruptable Power Supply with integral batteries . I am using a make
APC=American Power Corporation , model Back-ups Pro 650 (650 Volt * Amp or
650 VA ,which equals 650 Watts when power factor =1) Back -up time at full
load is approx 15 minutes. UPSes are also available for connection to
external batteries .

Major problem with that idea is the fact that Paul has no way to
calibrate or adjust the VCO. That's why he wants to start with a crystal
oscillator. If it works, he won't have to calibrate it.

With good control of charging current and voltage, the battery can
"float" in the circuit, always connected to the charger or the AC mains
low voltage supply that can take over from the battery when mains are
hot. The space folks do that regularly from low earth orbit (90 min.) to
geo-synchronous (24 hours), using series power diode isolation.

Another thought is to check out computer UPSs which have already
been engineered and tested, ready to go off the shelf. Those can
handle up to 600 W loads for small servers and auto-switch to internal
batter in less than an AC cycle. Industrial-strength UPS models can
handle much more. A little, cheap UPS sits between my PC box and
line all the time now, can easily handle 300 W loads for several minutes.

I thought he wanted a VCO so he could sweep the range from 40.5MHz to 41MHz.
Using a frequency counter, it would be trivial to tune this circuit to start
wherever he wanted. Frequency counters are cheap on ebay:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=3079423836&category=48701

Using a crystal oscillator would obviously be better, but it sounds like he
is having trouble getting the range he needs out of it.

Here is my survey on which I based my targets:

Release-ms
Receiver Attack-ms Slow Medium Fast

AOR AR7030 2/8 SSB/AM 1800 400 -
Collins 75S-3B/3C 1 600 190 -
Drake R4C 1 1000 350 50
Drake R8B 1 2000 300 -
Grundig Satellit 800 1 3000 300 -
Rockwell/Collins HF-2050
<30 3500-10000 250+/-50 -

U.S. Federal <30 800-1200
SSB/ICW modes
Telecommunication
Recommendation 1050-1998
"HF Radio Automation
Link" <13
<25 Data Mode

Design Target 1-13 1800-3000 300 <25

I wonder if there is any merit in making the attack selectable within a
range of 1-30 ms.

Traditionally, the circuitry was too bulky to make it more complicated,
so there was always tradeoff. With semiconductors the added circuitry to
make attack and decay independent doesn't require much space, or added
cost. Once one has that in place, one can fiddle with the actual times.

Maybe making it completely variable is not useful, but it'll only cost a switch to add multiple times.

Doug,
This is not the circuit you are thinking of but the Fremodyne is a one tube superhet. One triode of a 12AT7 is the local oscillator, the other is a converter/super-regenerative detector at the I.F. frequency. Several radio manufacturers produced them as low cost fm receivers in the late 1940's.

Antique Electronics Supply has good replacement tubes -- but solid-state regulators for old tube equipment is more fun, kinda like putting EFI on your flathead Ford engine (no kidding, it's done).

-- snip more --
> With a 6.3 V filament arrangement, that would be on the hairy edge

> room.

I would use a new LDO regulator, if I used one at all. On thinking about it after my post, it occurred to me that for the filaments I would be happy with a well-filtered DC supply to keep the filament hum from modulating my RF. If all you have is a 6.3V supply you need really low-drop diodes, however, and your filament transformer's RMS current will go up no matter what.

But can decrease cathode life if the cathode current is high -- even oxide cathodes don't like being temperature starved. Check some of the warnings and recommended start up procedures for 10kW transmitter tubes for some _really_ tight cathode care-and-feeding instructions.

Len,

You are right about the UPS, but the car batteries are already here as is enough stuff to probably build a suitable charging supply with.

There is one thing which should not stop around here, I just found that out the hard way, and that is the water pump for my hot water solar collectors (she blows like a whale!).
But once I buy that rather expensive DC circulator pump (only 1.5 amps) everything can run off that old battery.

I guess the only thing left to do is to find a little circuit which provides that good control you mention so that that battery can really be left on the charger for good (I hear people commenting that some charging circuits do get confused when they are hooked up to a battery which in turn is providing power to a load but I don't understand why that is).

regards Uwe

I'm mutiplying up and mixing down this time so getting enough spread
should be a piece of cake this time. The problem with your LC solution
is stability. This will be used for far field measurements at about an
eventual half-Watt output. I don't want to risk straying out of band,
but I do need to probe right up to the edges of it. The sweep
frequency will be controlled by a DC triangle generator voltage
applied to a varicap used as part of the crystal loading. I've
contrived it this way so I can carry out the mods on the filter
without having to keep going back and forth to the TX to vary the
output frequency. Yeah, maybe it's overkill but I've got the time
right now and nothing better to do. :-)

One thing to keep in mind is that battery voltage changes with temperature, and any float or trickle charger that doesn't take this into account can shorten a battery's life considerably. So if you want to get the longest life from your battery, you should make sure the charger is properly temperature compensated.

> charger is properly temperature compensated.
==========
Roy , If the lead acid battery charging current is limited to 0.1C ,(example a 15Ah sealed battery is charged at max 13.8 V with a current not exceeding 1.5A) is temperature compensation then still a necessity to optimise the battery's (usable) life ?
And if it is, in which temperature range ? I have not found this info through Web based tutorials.
I am very interested in this topic since I charge a number of batteries (some non- sealed some sealed) by means of a (150 W max)wind generator and 2 pcs 64Wpeak solar panel.

TIA for any advice

That would be cost-prohibitive ... to tool up to make the parts in obsolete
packages
that the production line is no longer using would cost a fortune.

What "angst"??? SMD parts are not "hard to work with" - they just require
that you learn and use different techniques ... the ARRL has some very good
material on their website on using SMD parts.

Frank, the biggest brownout I experienced, I guess one could call that already a black out, lastet 2 weeks and was unusual.

These days they can last anywhere from 0.0001 minutes to 10 hours.
The nice thing about the car battery approach is that if things take longer you can use the battery out of your car or truck, you could even drive around the block until a weak battery is recharged.

To add to Roy's and this comment.

The lead acid battery has the characteristic (Others don't) that you can put a constant voltage on it and it will charge itself up (good) and not over-charge (bad) itself. This is called "float" charging. Phone companies and cell phone systems use this. Roy points out that this voltage varies some as the battery temperature changes (I think it goes down cold, not sure). @ room temp (~72 deg F) this is about 13.6 - 13.8 (I think I have mine at 13.7) for a 12 volter.
Your Sears will, most likely, over charge. If it is the transformer, rectifier type, it is not regulated and does not float. It has half wave pulses so even if the meter (If it has one) shows low current, it consists of higher pulses at 120 pps.
A regulated supply will work and if it is always near room temp, you are ok.

Two other caveats. You need an accurate meter and all bets are off for old-weak batteries. I can't comment on what happens to the float voltage to an auto battery that "won't crank"...Sorry

By the way. On Lead acid only, you can measure the terminal voltage to determine the level of charge BUT the battery must have "rested" for some time before. That is NO load and NO charging. Don't know for sure, but I

suspect an hour or two is ok. I don't have ...

(Boy! this guy's full of "not sure" information ain't he?

... the exact numbers for a dead 12V. battery is a little under 12 V, I use 11.9) and a fully charged one is a little over 13V, I use 13.2. You can find numbers with a web search. I got the data sheet for the batteries I have (Gell Cell) Linear interpolation in between gives the% charge.

I should have added to the above that my 'renewable energy' charging voltage
will never exceed 13.8 V.
If the batteries are charged to this voltage level any energy generated by
wind generator and/or solar panels will be 'dumped ' via a number of car
headlight bulbs, by means of a simple opamp/ transistor circuit driving a
number of pass transistors.

Absolutely right, Carl - it ain't gonna happen.

A very good article in 'Communications Quarterly' (RIP) explained how the IC samples system works. Basically the economics of complex ICs are the same as for developing a new drug - most of the selling price is aimed at recovering the large upfront development costs. By comparison, once the line is set up and rolling, the *production* cost of the actual parts (or pills) is often quite minimal. It's a very good investment to give away samples as bait, if they're going to help reel in orders for large quantities.

Analog Devices (and also Maxim) are very clear that samples supplied to amateurs are much less likely to bring in orders than those supplied to commercial developers... yet they do it anyway, for the public good, and because it doesn't cost them much. And we're very grateful for it.

But that's as far as their charity extends. As Carl says, nobody is ever going to provide free samples of anything for which there's no commercial market.

Frankly, it's also as far as charity to amateurs and other experimenters *should* extend. They are not in business to featherbed us.

Fortunately, most amateurs have a "can do" attitude towards SMD. This just arrived on another mailing list:

>I broke my neck a few years ago and due to nerve damage my hands don't
>work as well as they did but I was able to do the mod
[which involved SMD work on a $2000 transceiver]
>without much trouble. I did it before the rig had even been on the
>air, brand new out of the box, scary, yes but worth it.

I'm proud to be in the same ham community as that person.

It is the 13.8 voltage limit which must change as the temp changes. The
current limit, I believe, is less of a problem. The lead acid should be
able to take quite high current when it is still charging (in need of
charge) - when it is, it is converting the current into chemical
stored-energy.
This is what the common 'Sears' chargers do. Hit 'em with volts to get
lotsa' current to charge them quickly and make the human responsible for
"stopping at full charge".

--
Steve N, K,9;d, c. i My email has no u's.

When it reaches full charge, then it is producing H & O while decomposing
the water -- and probably heat.

> Frank GM0CSZ / KN6WH

I'm sorry, but I don't have an answer to your question. Actually, I'm not sure there is a simple answer. There are a number of quite different types of lead-acid battery, with different plate compositions, construction, and electrolyte form (e.g., liquid and "starved" -- as far as I can tell, gelled electrolyte is no longer used or is at least very rare, in spite of the fondness hams have for dubbing every sealed cell a "gel cell"). Each has its own characteristics, advantages, and shortcomings. I heartily recommend a careful reading of the manufacturer's recommendations for the particular battery you'll be using.

In more general terms, I don't think any lead acid battery manufacturer recommends constant current charging at any level. Charging to maintain a cell at full charge (float charging) is, in my experience, invariably recommended to be constant voltage, not constant current, with the voltage being temprature compensated (lower voltage at higher temperature). The amount of current is then whatever the battery requires to maintain full charge.

I did a quick google search of

lead-acid battery float charging "temperature compensation"

and came up with quite a few hits including some basic tutorials, a couple of which were http://www.powerstream.com/SLA.htm and

http://www.emrg.ca/ideas&info/gel_cell/battery_care.htm. There are many more available. But again, batteries can differ quite a great deal, so you should really get information specific to the particular battery, or at the very least, to the general class of battery, that you'll be using.

This was probably the discussion I triggered on the Reciprocating Detector. I had intended to migrate my proto-board version to a more rf friendly board this Winter but still have not done so. I have done little home brewing and even less experimentation with detectors so can't really provide much perspective. I thought it worked well on SSB with carrier, such as CHU, but it
seemed to null the audio at centre lock on DSB signals - as though the sidebands were demodulated with opposite phase. Thought it might have been a consequence of the strays on the proto-board because I am the only one to have observed this phenomenon with the RD, ttbomk.

Additionally its self-oscillation frequency pulled on strong bass modulation towards the sideband of SSB suppressed carrier - a kind of FM distortion. It likewise was pulled by strong ICW signals.

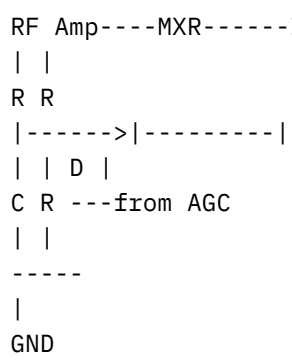
That's interesting, Steve but the circuit looks like this:



Just noticed an asterix by the 'delay' Diode that says it may be replaced by
a test-selected resistor - that's the way the DX-394 is done.

>("old" is when it doesn't get my Diesel started in subzero temps) are not.

While a cold diesel is hard to start, the capacity of a car battery
drops drastically at cold temperatures and assuming you are referring
to temperatures below 0 F (not 0 C), the capacity of the "old" battery
is well below nominal even in warm conditions.

So even if you can get those cheaply, you may have to have two to get
to the nominal capacity. The optimal float charging voltage may be
different for different old batteries and this can be a problem when
connecting multiple batteries in parallel.

Batteries designed for car starter duty often expect some amount of
vibration, which they do not get when in stationary use.

Unless you get several batteries for free, it is not such a big
bargain as it would look like. I don't know about the car battery
final disposal costs, but if they are high, collecting a large number
of reduced capacity old batteries might be quite expensive when they
are finally disposed.

==========
Uwe , With a normal AC system and long duration outages you mentioned an
appropriately sized UPS with external batteries would do the trick
(depending on the power you need)
For full domestic power requirements a 2-4 kWatt petrol or diesel engine
(portable) set would probably be the best.
Many of these sets have both AC and nominal 12v DC (for charging batteries)
Check the Honda range of petrol engine/generator sets ,often advertised and
mentioned by RACES and ARES emergency communicators and by those involved in
Amateur Radio Field Day operation.

"sweep" and "crystal controlled" seem to me to be mutually exclusive.
I once made a sweep generator for a specific job that used crystals
to generate frequency markers,(displayed on a scope). What
output/human interface are you
expecting?

I've substituted a ceramic resonator for the usual crystal to get more
'pull' over it. At the moment it's working well and I'm getting stable
output from 3.46Mhz-3.58Mhz which I'm very pleased with. Next problem
is to oust the variable trimmer cap and replace with suitable
varactor(s) for better frequency control...

I've not seen that magazine nor that particular circuit, but I do have a photocopy of "Project E10" (apparently from a set of projects?) with the title "One-Compactron Receiver - All Bands" and a footnote "Reprinted by permission of Popular Electronics magazine", but with NO citation.

FWIW, the particular compactron this article uses is a 6AF11, but it appears to be a one-stage regenerative receiver followed by two stages of audio.

For such a small circuit, it shouldn't be too difficult to regenerate the schematic; I did it once for an All-American Five.

>your flathead Ford engine (no kidding, it's done).

There still exist vacuum tubes off someone's shelf even though the
prices for small receiving-type tubes are $5 to $12 each (with any
sort of guarantee of performance)..

It was a bit of a shock to find those old, seemingly trustworthy OB2s
to be quite off specification, especially with the strike voltage off on
the high side. The receiver I was restoring was my own design and it
depended on the shunt regulator to help the stability of two local
oscillators that were L-C tuned, not quartz.

In the early 1960s and the conception of this receiver, regulation of
B+ (as we quaintly referred to HV then, heh heh) was only for expensive
things such as high-quality test instruments. A shunt regulator is fine
for critical things like oscillator stability but it does waste power which
is converted to heat, variable heat depending on AC power line stability.
Changes in local heating (within the cabilnet, chassis) means another
random variable to throw off oscillator stability. Series regulators waste
less heat (general statement, not an absolute) and can hold the HV
more constant over a wider current demand range.

I had accomplished a fairly sensitive and tuning-stable SW receiver
for my father using only 6 tubes for active devices, solid-state rectifiers,
and a single gas shunt regulator. Filament power was a mere 7.6 W
total; a common 5Y3 rectifier needs 10 W for its filament by itself (2 A

at 5 V). Internal heating was minimal and there was no such nonsense
as "waiting for it to warm up," to reach some thermal equilibrium above
room temperature. That "warm up wait" doesn't assure anything about
internal radio stabiity since room temperature may be variable and the
internal power dissipation varies with everything from AC line voltage
to plate current variation from AGC stages changing with signal
strength.

Tube series regulators waste power (and thus dissipate heat) because
the cathode-plate voltage is relatively high to stay within a linear
operating range. NPN transistors are more forgiving for series regulation
work since their emitter-collector voltage can be lower for the same
series current. Two NPNs in my prototype series regulator (plus one
zener) waste only 5 W for at least 2% voltage stability over AC line
(I can tweak that to at least 1$), An OB2 shunt regulator wastes 1.9
W alone and the total dissipation from all in the old supply is about
8 W. I'm already ahead of the game in reducing wasted heat by going
to transistors and zeners.

>RF. If all you have is a 6.3V supply you need really low-drop diodes,
>however, and your filament transformer's RMS current will go up no matter
>what.

I had NO "hum in the RF" to begin with...the filament regulation is an
afterthought since varying filament voltage in small receiving tubes used
as oscillators will result in varying fixed-tuned frequency. How much
variation depends on a whole bunch of other factors of the oscillator
circuit design. Using a variable autotransformer for AC mains adjustment
may lead to (sometimes) shocking discovery that 6.3 V filaments do
NOT stay at 6.3 when the AC mains varies +/- 10%. Frequency
counter measurement of the LOs in my case showed some drift with
AC mains voltage change that could only be accounted for by the
filament voltage changing.

The 7800s (positive) and 7900s (negative) all-in-one series regulators
are very common. Their minimum voltage drop for regulation specs is
only 2 VDC for most in each series. Minimum extra space, minimum
components added. Using a negative output and regulator yields
a stable bias supply which can be applied to other circuits or additions.
The 7800s and 7900s are legacy devices and still in production.

>> Note: The original AC filament voltage was made within certain
>> (seldom specified) limits; if that is on the low side also, the 7806

>cathodes don't like being temperature starved. Check some of the warnings
>and recommended start up procedures for 10kW transmitter tubes for some
>_really_ tight cathode care-and-feeding instructions.

MOST homebrew projects involve lower power. Running 6.3 V NOMINAL filaments at 6.0 V isn't going to degrade anything. In my case it has 12.6 V NOMINAL filament voltage reduced to 12.0 V exact. Filament voltages are always given as "nominal" since the indirectly-heated tubes almost always get their filament voltage from transformers. Since ordinary transformers don't regulate, the percentage change of secondary winding voltage is the same as primary winding voltage change....for most of North America that is 115 VAC RMS +/-10 V or about +/-10%. A 6.3 V filament-heater can thus range from 5.7 V to 6.9 V just from the line.

Reduction in the high-temperature thermionic devices' voltage will result in longer operating life. That was true over a half century ago. A friend of mine into model railroading has been running lots and lots of #327 28 V rated aircraft indicator lamps in his track layout, all running at about 18 VAC. NO outages yet due to filament failure in what must be about 3 dozen or so used for 35+ years. Still quite bright enough in ordinary room lighting.

I prefer solid-state all around, including LEDs. I'm keeping most of the vacuum guts of this little receiver still in vacuum tube style just for sentiment's sake. Everyone's mileage varies.

WA2ISE has a site that describes interesting mods to "All-American 5" AM radios, and the following URL discusses a 3 Compactron set. By changing the rectifier and detector to solid state devices, and either sacrificing IF gain and/or speaker output, it might be possible to squeeze all that into two triodes and a pentode, which is what's in a 6M11. It's not exactly what you're looking for, but it may give you or somebody else some clever ideas:

http://pw2.netcom.com/~wa2ise/radios/compaa3.html

W0PBV wrote elsewhere in this thread of a "Project E10, One-Compactron Receiver - All Bands" article in "Popular Electronics" magazine. This may be the article to which he refers:

Yet they DO start. :-)

I'm familiar with north country snow, ice, and freezing temperatures,
learned to drive in such environments. Automobiles are OUTSIDE
and have to take the entire change of temperatures. An emergency
power backup system does NOT have to have its battery out in the
cold...or hot.

>So even if you can get those cheaply, you may have to have two to get
>to the nominal capacity. The optimal float charging voltage may be
>different for different old batteries and this can be a problem when
>connecting multiple batteries in parallel.

Not absolutely necessary. 12 Volt automobile batteries designed
for LARGE vehicles have rather high ampere-hour ratings.

Do NOT - absolutely - keep batteries in parallel without series
diodes or other protections! One or more batteries in parallel can
effectively "cook" one that is low in voltage.

>Batteries designed for car starter duty often expect some amount of
>vibration, which they do not get when in stationary use.

Outside of bad design and poor quality control, the vehicle battery
source of failure is almost always excessive vibration. When plate
material is shaken off, it collects in the case bottom and can
short out neighboring plates.

>Unless you get several batteries for free, it is not such a big
>bargain as it would look like. I don't know about the car battery
>final disposal costs, but if they are high, collecting a large number
>of reduced capacity old batteries might be quite expensive when they
>are finally disposed.

At most auto parts stores in the USA, one can get a medium-size vehicle lead-acid battery for about $30 and trading in the old one. Prices vary slightly according to region and store. Factory-new batteries, such as Sears "Die-Hard" brand, are available for about twice that, no trade-in. Auto dealership-service centers will probably charge three times that (got stuck for that last year). There is a great variation in lead-acid vehicle battery cost over here so it is worth it to shop around.

My eye doctors' office uses two 12 V lead-acid vehicle batteries for its servers (6 opthalmologists, 2 optometrists)...but only because they have an old UPS designed for 24 V battery back-up. Last year they moved that UPS and batteries to a concealed cabinet instead of being beside the receptionists' desk where all who could see saw it. Much better appearance. :-)

By the way, a small 12 V lead-acid battery designed for motorcycles ought to be good for a heavy QRP rig.

I happened to discover a copy of the original IEEE conference paper in
my files here, and I see that the circuit requires that the input signal be
reduced to a half-wave rectified signal. The Ham Radio articles state that
it was difficult to achieve a faithful half wave signal. I know that I can
overcome this problem with my patented method of augmentation, which I have
used to make very linear 1W HF/VHF/UHF amplifiers. Another problem is that
the circuit needs to be balanced, and in the Ham Radio articles this need is
not faithfully implemented. Looks like there's lots of room for
improvement.

<< I have an old Heath SG-6 signal generator. It uses two triodes.
I'd like to convert it to solid state. >>

Bill-

Others have supplied more good suggestions than I thought were possible, but I couldn't resist adding to it.

With lower voltage solid state circuits, you probably will need additional amplification to provide the same output you now have. Keeping the output level constant over the entire range could be a challenge.

I seem to recall that there are high voltage FETs available that might be candidates for direct substitution for the tubes. Keeping in mind that a reactive load could stress the FET at double the supply voltage, you might have to reduce B+ slightly.

The suggestion to regulate B+ seems a good idea, but perhaps you only need to do it for the oscillator triode(s). I once replaced a 105 volt VR tube in a Heath HW-100, with a ten watt zener. It was a reverse-polarity diode, so the stud mounted directly to the chassis. That approach might be easier than regulating higher current for the entire circuit.

If you try the approach of keeping the tubes with a regulated DC filament, I wonder if a vacuum tube would be susceptible to the same "filament notching" that panel lamps experience? According to a report I read many years ago, it seems that lamps operating from DC fail sooner on average than lamps operating from AC. Failure analysis showed a notch in the filament develops only on the DC lamps, with failure occuring at that point.

Today there are more really good kits out there then there have ever been. But you need to ask yourself just what are you looking for?

Probably Elecraft is the Cadillac of kits these days ... www.elecraft.com, but their stuff is a little high end. If you are looking to melt some solder after a long hiatus, they may be a little more than you are looking for. On the other hand, their quality and documentation puts the old Heathkits to shame.

Small Wonder Labs has some very nice, lower priced kits www.smallwonderlabs.com. Their stuff is closer to the other end of the price spectrum, but still very highly regarded. Their SW+ series is simple, and has the added advantage of lots and lots of documentation on the net, if you want to re-learn what these things are all about. Their DSW series is one of the most lusted-after rigs among the backpacking set. It's a one man show, however, so deliveries are sometimes a little long.

The American QRP Club www.amqrp.org collects together the kits of a number of QRP clubs. These are often the best deals, but each kit is only available for a short period, so you might not find just what you are looking for at the time you are looking.

If you are looking at low cost and not necessarily the best quality, Dan's has a number of lower end kits www.danssmallpartsandkits.com. Dan's only takes orders by snail mail, so the turnaround is at least two weeks.

For the definitive list, www.qrparci.org/links.html lists many, many places to look for kits.

MFJ and TenTec have been mentioned. MFJ is more on the low quality end, but they are reasonably priced. TenTec has the famous TenTec support behind it, but in my opinion tend to be a little high priced for what you get.

Hope this helps.

Boy I wasn't paying attention.

I got the idea you were maybe looking for a receiver, and here is this thing, simple, cheap, unique.

The 9850 seems to be pretty popular. You can plunk one down on a DDS daughtercard from NJQRP or get one of the Far Circuits boards (although in my experience their quality is a tad spotty).

The Tayloe mixer can be fed with a 9854 and that looks like a fun experiment but the 9854 only seems to be available in impossible packages.

Joe,
You seem to be under the impression that SMD's are "new". I obtained my first "flat packs" in 1968. And they were surplus from some type of computer, at that time. Sylvania made them - SUHL was the logic family of these gates and flip-flops; I still have the two boards (less two or three ic's I pulled off to play with) and the data sheets. The data sheets indicate they were made in 1965 and 66.
They couldn't sell the package to anyone but military and commercial customers (neither of which ever wants their boards to be "hackable") then and the DIP became the standard for experimenters. Unfortunately, as you alluded to earlier in this thread, there is not much of an electronic tinkerer's market anymore. Now that more commercial apps. exist, the manufacters can force what few tinkerers there are to accept the more economical to produce SMD packages.
I readily admit that there are only a few options for experimenters when the cold hard facts are faced.
1) gripe and cease building at the cutting edge of ic technology as I have done;
2) buckle down and force oneself to say "SMD soldering is good for me- I deserve it."(I'm sorry, I couldn't resist);
or 3) look for other options - Dave, Mike W, and you have made some good, pertinent comments about daughterboards and adapters (a "Manhattan Style" adapter with the ic soldered on would be just as useable as a DIP adapter - if someone wants to take up Dave's challange.); just to prove that I'm not the old stuck in my ways fart that some probably envision me as, I am investigating DDS out a PCI or AGP slot of a pc (too bad video speed d/a converters are unobtainable.) ;-).
May the hobby continue to grow and be fun for all who find it.

The problem with diesels is the high compression ratio, so rotating
the crank shaft is the hard part. Just monitor the signal lights in
the dashboard when you try to start.

Running the block heater for half an hour will help a lot, since the
oil flows much more smoothly and the battery will deliver much more
current (if in the engine compartment) due to the higher battery
temperature.

In view of all the discussions for and against SMD , it might be useful to point at a component supplier located in Birmingham -England . He is Chris, G8CHW who I recently discovered as having more than 7000 items in stock , even Germanium semiconductors from the 1960s. Have a look at www.modecomponents.co.uk. You'll be surprised what's available,including RF components. He exports to the european continent ,although I imagine he would be happy to also supply US customers .
Another supplier from the Birmingham -England area is JAB Electronics ,who also have various items keeping the radio homebrewer happy : www.jabdog.com . They accept VISA/Mastercard.
Another supplier to check is Sycom , www.sycomcomp.co.uk

Conclusion : Here in the UK there are no problems with getting any electronic components at reasonable prices.

It isn't the purpose to transmit these tones!

What I want to do:
Talk over my portable tranceiver all around the house on a couple of
miliwatts.

When I press the PTT button of an extended home brewed microphone
the tone comes up the computer in my shack will set the big tranceiver
active and:
- filter out the tones
- retransmit my signal with the tranceiver

When I release the PTT another tone will be transmitted so the computer
knows to
switch of the tranceiver.

The same way nasa used this I wanna use it to, to remote controll the PTT.
So I can work over a bigger range with less battery power.

The major reason why I want to work with tones is that if outher people are
working
on "my" frequency my rig wil transmit. with the tone it only transmit when I
wan it.

I want to write a computer program that can accept DTMF tones and the "roger
beep" tones.
So I can choose the repeater or freqency I want to operate remotly.

A loss - for you *and* for those who might benefit from the fruits of your
experimentation.

> 2) buckle down and force oneself to say "SMD soldering is good for me- I
> deserve it."(I'm sorry, I couldn't resist);

I don't understand the "pain" aspect that folks keep citing ... I'm 53, "my
arms are
too short," and I've had corneal surgery that introduced some very irregular
astigmatism,
but I can still handle SMDs (at least down to 0403). Again, it's a matter
of learning
and using the proper techniques.

You need the following:

One of those adjustable lamps with the circular flourescent lamp and a
magnifier.
An eye loupe (10x) works well for me (for really close inspection).
A couple of small-tiped temperature-controlled soldering irons.
Some flux.
Some solder wick.
Some fine-tipped tweezers (almost needle pointed).
Fine guage solder (for use with the iron). Solder paste is best, though if
you're going to
do much SMD work ... I prefer the "no-clean" type with water soluble flux.

And, the best option, which I have, is a hot air reflow/rework station (I
bought one
brand new on eBay for $315 ... I also bought a "vacuum pen" which is the
easiest way
to pick up SMD parts and place them.)
Note that the hot air station and vacuum pen are NOT necessary to make SMD
work
painless - they are just niceties that I have chosen to invest in to make
the work even
faster and easier.

> or 3) look for other options - Dave, Mike W, and you have made some good,
> pertinent comments about daughterboards and adapters (a "Manhattan Style"

> the old stuck in my ways fart that some probably envision me as, I am
> investigating DDS out a PCI or AGP slot of a pc (too bad video speed d/a
> converters are unobtainable.) ;-).

You start kludging all sorts of adaptor boards into the brew and you extend
lead lengths,
making it harder to get decent grounding and introducing all sorts of wierd
impedance
"bumps" - you can get away with it on audio and things that run at really
low clock rates,
but you're asking for trouble with RF or high-speed logic.

> May the hobby continue to grow and be fun for all who find it.

Ah!!! Something we completely agree on :-)

The packaging is not "impossible" - it just takes some different techniques
to do the
soldering - read the QEX article on a DDS/PLL synthesiser in the latest
issue of QEX
and check out the SMT stuff on the ARRL website ... DIPs are all but gone -
that is
the reality, and other "through hole" parts are getting (and will continue
to get more and
more) scarce and expensive, as industry has gone to SMT in a BIG way
because:
1) it's better (preformance, due to reduced parasitics from leads, also more
reliable if
done right ...)
2) it's cheaper
3) it allows things to be build smaller
4) it doesn't eat up space on all the layers of the PCB for through holes

Texas Instruments beat Sylvania by several years with DTL. :-)

I held my first flat pack (from TI), a single DTL flip-flop some time
in 1960. Couldn't believe how TI had managed to cram all that
circuitry in there! :-)

TI beat most of the competition with its introduction of TTL to
replace DTL. Their 7400 and 5400 part numbers have gone into
legacy mode for functional equivalents made by others since.
Those numbers are so common that some CMOS ICs have the
functional-equivalent numbers in their whole part number. :-)

>They couldn't sell the package to anyone but military and commercial
>customers (neither of which ever wants their boards to be "hackable") then
>and the DIP became the standard for experimenters.

The original flat packs were excellent for stacking one on top of the
other in microwelded assemblies for spacecraft. JPL and one maker
of diallyl phthalate plastic holders came up with a kind of "super DIP"
that took the flat packs and etched-copper-foil-on-kapton-film as the
interconnect wiring.

The enemy of the flat packs and first ICs was CO$T. TI and every-
one else had to recoup their ramp-up and development costs and
almost shot themselves doing that. The single DTL flip-flop I held in
1960 cost $24 each! It was cheaper for the mainframe computer
makers to use discrete bipolar circuits than go to DTL and the flat
packs or even to TTL in flat packs. The big break was the
convenience of the dual-inline package and standardization on the
early 0.1 inch layout grid.

It's difficult to hack out welded-in-place flat packs. Many were so
mounted on flat PCBs back before wave-soldering was practical.

A big, big break for hobbyists was RTL from Fairchild. In little round
epoxy bipolar-size packages, those were affordable across the shelf.

My first frequency counter was built from Resistor-Transistor-Logic back in 1968-1969. Cost was prohibitive then to go for TTL in the new DIPs. Problem was that TTL out-performed RTL in speed and ability to progress from SSI to MSI even in the old, original TTL medium-speed family. Once 54H and 74H appeared, RTL was a goner. Mainframe and minicomputer designs standardized on TTL (to TI's delight, no doubt) and the other industrial applications picked up on that. TTL prices dropped. Even more when the 74LS family appeared with PDIP. 74LS became the family of choice for the first microcomputers' "glue" holding them together circuit-wise.

>Unfortunately, as you
>alluded to earlier in this thread, there is not much of an electronic
>tinkerer's market anymore.

I disagree. All kinds of electronic tinkerer's suppliers in certain chain stores (Fry's Electronics in the southwest US has one whole aisle for packaged ICs) and many small mail-order dealers as well as the biggies such as Digi-Key, Mouser, and Newark. Legacy ICs, especially logic, is down to well under $1 per package in singles.

>Now that more commercial apps. exist, the
>manufacters can force what few tinkerers there are to accept the more
>economical to produce SMD packages.

Disagree again. SMT is not necessarily "more economical to produce" compared to DIP. The process is about the same. The driving force is FINISHED ELECTRONIC SYSTEM SIZE and the consumer electronics MARKETPLACE.

Industry estimates put cellular telephones (little two-way 1 GHz radios) at about 3 Billion worldwide. In the USA alone in 2002, the U.S. Bureau of Census stated that there were about 100 Million cell phone subscribers, or roughly one out of three citizens with those tiny "HTs". Cell phones are complex things and are appearing with more and more auxilliary features...the only way to stay in the cell phone market is to make them small and with tiny parts to cram everything in there.

I just replaced the thermostat in my house with a name-brand all-electronic unit having a little LCD indicator (very easy to read, momentary back light) and electronic thermal sensor, battery powered so it won't lose its settings plus several other perqs not possible with the 40-year-old bimetallic strip model. Neat little SMT PCB, no crowding of anything. It is less than half the size of the old one yet has more features.

The MARKET drives certain things, especially so in consumer electronics.

> I readily admit that there are only a few options for experimenters when
>the cold hard facts are faced.

I don't. Looking back over more than a half century of electronics hobby activity the options are FAR more NOW than back then. It's been growing and branching out all that time.

The "cold hard facts" for SOME "experimenters" is that they can't adapt to using semi-discrete ICs in readily-available DIPs but want an all-purpose IC to do the DDS functional dirty work. The heart of a DDS is basically a curious accumulator that must work in a flexible way (several variations on the theme)...that is different than the PLL counter which is just a preset-by-external-control to a fixed countdown. Both share a phase-frequency "detector" (logic circuit) which can be one of two general kinds. The DDS principle is vastly different because of that flexible accumulator and hard to grasp for most folks (took me a long while to get comfortable with it). It takes more wiring in discrete logic than a PLL but both the DDS and PLL can be done that way. "Experimenters" don't always need ultra-small-sized sub-systems for frequency control.

Analog Devices (and some others) have collapsed most of the frequency control sub-system into a single IC. We should ignore the package size and be grateful that one IC saves a lot of discrete packages and wiring. ADI's manufacturing choices are basically market-driven, not "experimenter" driven. There's no guarantee that every ADI IC model will survive in the near future...just like all those other "legacy" ICs, mostly analog, of two and three decades ago that aren't made now. Of about 8 variations of a MOS PLL IC that Motorola made a decade ago (MC145nnn family), only one survives today, the MC145151. Motorola couldn't sustain the cost of continuing to produce something that didn't sell. [Motorola semi split also, but that's another story]

>1) gripe and cease building at the cutting edge of ic technology as I have
>done;

"Cutting edge technology" doesn't require smallness. FUNCTION is the cutting edge. A 5" x 8" PCB DDS made with ordinary logic ICs has the same function as a 1" x 1" area on a PCB done with 1 IC.

>2) buckle down and force oneself to say "SMD soldering is good for me- I
>deserve it."(I'm sorry, I couldn't resist);

An HF-range frequency control sub-system can be made with legacy digitial logic devices off-the-shelf in DIPs. If anyone insists on SMT then they have to get that silly little millimeter soldering iron tip and learn how solder in a small way...or, be inventive like a robotic hobbyist who converted an ordinary toaster-oven into a reflow oven for soldering 60-contact ICs with toothpick-applied solder paste.

Whichever way the construction is done, the prime driver is still FUNCTION.

>or 3) look for other options - Dave, Mike W, and you have made some good,
>pertinent comments about daughterboards and adapters (a "Manhattan Style"
>adapter with the ic soldered on would be just as useable as a DIP adapter -

>if someone wants to take up Dave's challange.); just to prove that I'm not
>the old stuck in my ways fart that some probably envision me as, I am
>investigating DDS out a PCI or AGP slot of a pc (too bad video speed d/a
>converters are unobtainable.) ;-).

"Video speed" D-to-A converters are available. Off the shelf. There's
at least three in every HDTV receiver today. :-)

>May the hobby continue to grow and be fun for all who find it.

Heartily AGREE on that!

I'm pretty comfortable with SOP's and can get along with a TSSOP's, although I can't say I like it. In that article, he used TQFP's which, although I haven't yet had the need, I suspect I can deal with. I use the same technique for TSSOP's that he describes in the article.

But when I tried to order samples of 9854's the other day, the only choice was BGA's. I have no clue how to deal with them. Yeah, solder paste and an oven MAYBE, but without machine placement seems like a crap shoot.

You can say that "182" as "a 1, an 8 and then 2 zeros, picofarads." So
that's 1 8 00 pF, which is the same as John's .0018uF.

1681. Homebrewed remote antenna switch.

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-02-29 22:57:57 UTC
From: James W <change-to-jw22-at-trlp-dot-com@trlp.com>
Message-ID: <1044rjltoqnro85@corp.supernews.com>
Source record: 28168

I'm just starting to think about building a remote antenna switch.

Since I've never played with one of these before.. I'm a bit concerned about what to look for in relays. I'd guess I want SPDT, so that the antennas that are not selected can be grounded. Other than that, I have no idea on what specification I should look for.

I want 12V coils. I need contacts capable of handing ~150W, and just to avoid cooking relays, I guess I need to be concerned about SWR. The antenna switch will be between the exciters and the antenna tuners, to SWR 'should' be low (<2)

Any suggestions on relays?

I, and now to embarrass myself... I'm a bit concerned about the feedline connections.. Most of the antenna switches I've seen, simply connect all the feedline braids to the bulkhead, and run the center connectors to the relays. So.. what does this do to the characteristic impedance of the feedlines? I guess this is the same thing that takes place inside the exiciter, but I just wonder if I need some type of transformers or something..

thanks es 73s

Actually, the 16-pin PLL chips are TSSOPs, while the AD9852/AD9854
packages I used are considered "LQFP" packages. These are a little
thicker than TQFP but are otherwise pretty similar. The DDSes have the
same spacing between pins as the TSSOPs (0.5 mm) but more of 'em (80).

That's not good news. BGAs really *are* the end of the world for
homebrewing as far as I'm aware. I have not heard of any techniques for
soldering them by hand.

Interestingly, though, having just checked FindChips.com, Digi-Key
appears to be selling both AD9852ASQs
(http://www.digikey.com/scripts/DkSearch/dksus.dll?PName?Name=AD9852ASQ-
ND&Site=US) and ADF4112 PLLs
(http://www.digikey.com/scripts/DkSearch/dksus.dll?PName?
Name=ADF4112BRU-ND&Site=US). That *is* good news. I'll have to go
update the article page.

I have a reciprocating detector (RD) kit that I purchased from Stirling Olberg, W1SNN, in the early 70's. I have built it into a broadcast band AM receiver to eliminate selective fading distortion. This receiver has switch selection of diode, quasi-synchronous and RD detectors. I could probably run some tests for you using this receiver.

I can also provide a bibliography of articles on the RD if you do not presently have one.

All prices are in US Funds.

QTY. Part # Unit Price Description
---- --------- ---------- -----------
OPTO.

54 TIL311 $7.00 ea. The TI TIL-311 is a Hexadecimal Dot
Matrix Display with integral TTL driver
electronics to accept, store & display
4-bit binary data, Epoxy package
(Note: This part wholesales at about $16.50 each)

8 TIL311A $7.00 ea. The TI TIL-311A is a Hexadecimal Dot
Matrix Display with integral TTL driver
circuit to accept, store & display
4-bit binary data, Plastic package

11 DIS1417 $7.00 ea. The TI DIS-1417 is a Hexadecimal Dot
Matrix Display with integral TTL driver
circuit to accept, store & display
4-bit binary data, Epoxy package

For a copy of the TIL311 Datasheet see:
http://www-s.ti.com/sc/ds/til311.pdf and it is mirrored at
http://umwnt1.physics.lsa.umich.edu/mttc/images/til311.pdf

275 Green LED $0.10 ea. Rectangular 5mm x 2mm face/lens
$17.50 per bag of 250 ($0.07 each) and

7,250 Red LED $0.10 ea. T1 3/4, 5mm Diameter or 0.2" Diameter
Sharp P/N: GL5PR4 (5mA at 1.9V)
$17.50 per bag of 250 ($0.07 each) and
$100 per box of 2000 ($0.05 each)

106 MAN6440 $0.95 ea. Dual Digit, Green 7 Segment display,
0.56" tall character, Common Cathode
$15 per tube of 20 MAN- 6440 ($0.75 ea.)

85 FND6740 $0.95 ea. Dual Digit, Red 7 Segment display,
0.56" tall character, Common Cathode
$15 per tube of 20 FND-6740 ($0.75 ea.)

TTL CHIPS, DIP Package

525 7407N $0.18 ea. $4.00 per tube of 25 ($0.16 each)
Hex Non-Inverted Buffer with
Open-Collector outputs

605 74ALS20AN $0.19 ea. $4.00 per tube of 25 ($0.16 each)
Dual 4-Input Positive NAND Gates

240 74ALS27AN $0.19 ea. $4.00 per tube of 25 ($0.16 each)
Triple 3-Input Positive NOR Gates

1,325 74LS74AN $0.25 ea. $5.00 per tube of 25 ($0.20 each)
Dual D-Type Positive Edge-triggered
Flip-Flops with Preset and Clear.

100 74ALS74AN $0.25 ea. $5.00 per tube of 25 ($0.20 each)
Dual D-Type Positive Edge-triggered
Flip-Flops with Preset and Clear.

RESISTORS

55,900 100 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$15 per box of 5000 or
$100 for 50,000 pieces.

3,400 220 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$12 per box of 3400 or

3,400 680 Ohm, 5%, 1/4 Watt Carbon film resistor, $1 per 100,
$12 per box of 3400 or

A pack of 100 resistors is $4 inclusive shipping to anywhere
in the US and Canada

e-mail: jrparts@excite.com

Minimum purchase $4 including postage.

No shipping is included in the above prices. To quote a
total including shipping, I require your full ZIP code or
postal code in addition to a list of what you are interested
in. Please specify the country for international orders
outside of North America. The shipping you will be quoted
is the cost of the postage stamp (plus insurance if requested).

The only part that I will ship for a total of $4 (by regular
mail) to anywhere in the US and Canada is a pack of 100
resistors.

All components are new. All semi-conductors are stored in
anti-static tubes/bags or on anti-static foam if you purchase
less than a tube/bag.

Offers on the lot are welcome. Keep in mind that I am looking
for a price below wholesale, but more than the commercial buyers
of surplus electronic parts are offering.

With BGAs you HAVE to reflow solder ... however if the prep is right, they
should
"self-center" (as do most SMDs) on the pads if you're close enough - it's
interesting to
watch manually placed SMD resistors, caps, etc. actually move an center
themselves
up on the pads due to surface tension effects when the solder reflows ... IF
the pads
are well-designed and balanced.

Hi
I have the MFJ 989C, and I am noticing that I can tune antenna to low SWR but I also have noticed that the SWR often was jumping or spiking and very unusual. I thought it may be coax or antenna or a short but then I noticed also that the inductance coil is very sensitive. If you touch it or tap it this will cause the SWR to spike. Also when it spikes, if you put a little pressure on the Inductance coil knob it will solve the problem. Anyone else have situation such as this? What did you do to fix the problem? I opened it up and cleaned the contacts where I thought the problem was but still didn't correct the problem.
Any ideas ???

Evan

The question is, what are you trying to do?

ADIF is a file format. It is well documented, and it can be produced with any text editor. Lots of places have the docs, but www.hosenose.com/adif/ seems pretty good.

The ADIF spec, unfortunately, leaves quite a bit of room for interpretation. Different implementors interpret it a bit differently, so you may have a little trouble moving something from one application to another using ADIF.

If you have a paper log that you want to convert to ADIF, most of the logging programs support ADIF exports, although maybe not all the freeware ones. Still, look for any of the popular loggers.

You said you wanted to do some "log file combining". If you have a logger that imports and exports ADIF, simply stick the files together with a text editor. The format is a text format, and if you open an ADIF file with Wordpad it will be pretty obvious what is what.

1. Check the contacts that you _don't_ think are the problem. Just because it's a roller inductor doesn't mean that you're not the victim of a garden-variety cold solder joint or a loose rivet. I'd check the whole current path from one solder joint to the other (including the other moving contacts -- there's a slip-ring _and_ a roller, yes?).

1a. You might want to try measuring resistance while you wiggle the thing to see where the problem is. This can be difficult and frustrating, but if you manage it you'll know for sure where the problem is.

2. _Only_ after you've verified that it isn't something else, see if you can increase the contact pressure on the questionable joint. I'd think long and hard before I did this on my own equipment, because it'll make it wear out quicker.

I had a problem similar to this with a tuner I bought from a guy at a fleamarket some time ago - a homebrew SPC based on the design in the ARRL handbook of a few years ago. The tuner was worse off than your MFJ - it was jumpy during transmission, _and_ very difficult to get to tune to a low SWR at all.

The problem turned out to be the roller inductor, which (like most of the other parts he'd used) had been recycled from older equipment. It turned out to have two sets of problems:

- The contacts at the end of the main roller were badly gunked up, with dirt and with some form of old lubricant. There was a similar amount of gunk in the bearing area where the contact wheel slides back and forth on its support rod.

- There was a significant amount of pitting on both the contact wheel, and on several sections of the wire on the inductor. I suspect that the previous owner of this inductor had overstressed it, causing arcing which pitted the contact area.

Fortunately, I was able to fix it completely with a bit of effort.

I started out by cleaning all of the dust and dirt off of the roller inductor, using a combination of isopropyl alcohol, and some Caig DeOxIt spray, and wiping with a clean cloth. I also cleaned the contacts at the end of the roller, spraying with DeOxIt and then using cloth to soak up the gunk which had been flushed out by the spray. I repeated this process until all of the contact areas had been flushed out, and no longer emitted any amount of black goo when sprayed. Finally, the contact wheel's central bearing (where it slides/rolls back and forth on a metal rod) needed to be flushed out in the same way.

Fixing the pitting on the roller contact wheel and the wire was the next task. The wheel was easy - it's solid silver, and I was able to burnish it and restore a flat contact surface with a small riffler

file. I used the same approach to buff off the pitting on the roller wire, but in doing so the silver plating on the polished areas was removed and the underlying copper was exposed. I could have left it that way, and just cleaned the wire more often to avoid oxidation, but instead I decided to buy a small silverplating kit (from www.caswellplating.com) and re-plate the wire. Doing so took only a few minutes once I had the kit.

I finished up by giving the wire another cleaning with isopropyl, and then sprayed a small amount of DeOxIt on a clean cotton cloth and wiped down the wire, the roller contact surface, and the metal rod on which the roller slides back and forth. This left all of the electrical-contact surfaces clean, lubricated, and with a thin film of antioxidant protection.

The results were everything I could have hoped for. The "jumpiness" of the roller inductor is completely gone. Once tuned to a low SWR, the SWR stays low during transmission. Fine adjustment of the inductor control result in an easy, smooth change in SWR / reflected power.

Source record: 28186

Hi all,

I've occasionally been using the AADE Filter Design software
evaluation version the past couple months, and thought I'd splurge and
spend $25 on it...definitely worth it. But I discovered that I can't
do that now. Now it's free for the downloading.
http://www.aade.com/filter.htm

Thanks to Neil for providing such a great price/performance ratio on
this product. My only connection with AADE so far is as a user of the
previous eval version of Filter Design.

Cheers,
Tom

Sewing stores have big magnifiers on arms for people doing needlepoint.
They work very nice.

Time to play with a PIC? Use this for PTT delays and the
two tones system or to generate timing and a CTCSS tone.
I prefer the latter. Of course this could be done discretely
for CTCSS using many forms of oscillator and logic.

I've done a fair number by hand @ work. They self center nicely, and
don't really require any solder other than the balls. Just some fresh
liquid flux and a heat gun, and a little practice. They do self center
nicely. You can also reflow in a toaster oven if you really want to.
(Not the one in the kitchen, please!).

On my first attempt using a recently purchased alcohol still, it took over 6hrs to make around 4 liters of alcohol. We were running the temp steady at around 84 degs. When I finally decided to increase the temp to 90 degs is started flowing faster. Should we have ran it hotter from the start. How long does it usually take to run off 5ltrs.

Any tips would be appreciated

Thanks xpyttl for your help. I did what I needed to do. The reason for my 1st post was that an explanation I got suggested that I needed to get ADIF from an external source.. However, upon more research, I found that ADIF was already on my logging program. And I exported two log files into ADIF and then imported them into a log file to make one log.

Well, it appears that in at least one respect .au law _does_ differ
significantly from .us law.

This group, however, is a _radio_ homebrew newsgroup, not an _alcohol_
homebrewing newsgroup -- although some of us resort to alcohol to
recover from the problems inherent in the radio kind of homebrewing.

Just remember that the first 5-10% and the last 5-10% of your run will
be full of things like fusel oils and methanol, and should _not_ be
consumed.

You can still brew it here in the US, but only for personal consumption,
your are allowed 2 or 3 gallons a month per person or each family member.

Best thing to get the info you are looking for is to go to goggle and do a
search for homebrewing.

From personal experience, use the lowest temp, be careful not to scorch the
mash. I was raised in the hills of eastern Kentucky where everyone brewed
their own.

Back when I was first licensed, I lived down near the corner of Ohio, West Virginia and Kentucky. There were many, many late night QSOs on 6 meter AM. Some of them old boys back in the hills used to have great stories about the revenuers that seemed particularly appropriate in the wee hours.

So, maybe for me it sounds like it is on topic:
rec. --- ummmm, yeah
radio.amateur. --- yeppers - brings back memories
homebrew --- oh yeah

..

Well guys, thanks so much for all this info.

I couldn't access this newsgroup for a few days (server problem) and now I had a whole bunch to read.

First of all in my economic environment (out here in the country) used batteries, their disposal etc. cost next to nothing. Everything else, UPS etc. does cost money.
So good (except for the cold cranking problem, and I will try out the hair dryer routine, I don't discard advice from people in Alaska lightly) batteries of this type will be used. And as Avery pointed out when everything fails even a new battery is quite a bargain.

I read some of the material Roy recommended and it seems that if I keep the battery mostly at constant temperature, and sitting on a cement slab which is heated one can assume relatively constant temperature I would think, I could keep the battery charged (good enough for my purpose) if I attach a voltage limited charger with 13.7 volts.

A battery like that would run a DC circulator pump for days (a pump like this could use 4 amps but it is only ON when the sun is out).

Um, David? Perhaps you should read the group name. This is an amateur radio newsgroup, not a group for homebrew alcohol (or other recreational chemicals). We do get the occasional posting here on those topics, but they're relatively rare.

OTOH, yes, the hotter you run things, the faster they will go, but you'll also carry over more water. That's an advantage of a fractional distillation column, but I suppose you don't have that. You can also make things go faster by increasing the surface area of the liquid in the vessel you're heating: a bigger still. It would also go faster if you pulled a vacuum on the output end, but then be sure to run your condenser cold enough to pull the ethanol out.

Better check that. When I started brewing beer in 1980 the law was that you could brew _beer_, but you couldn't distill _anything_ unless it was for fuel and denatured at the catchbasin.

The advice about the first and last of the run is sound, and if you're tight for cash molassas from the feed store is a lot cheaper than buying malted grain or extract (of course, if you know how to malt it yourself you'll do just fine).

1714. ARRL bamboozled by FCC -- BPL Lives, big money talks

Newsgroup: rec.radio.amateur.homebrew

the following article appeared in today's Wall Street Journal. Perhaps the suits in Newington believed their own BS. Not a single mention of the interference issues and a whopping endorsement by the FCC's chief engineer.

The Web's New Outlet
Utilities Plan to Send Internet Service
Over Electric Lines, Challenging
Cable Modems and DSL
By KEN BROWN
Staff Reporter of THE WALL STREET JOURNAL

In an age when consumers can choose from 500 TV channels and nearly a dozen phone companies, most who want high-speed Internet access have at best two choices: the local phone company or their cable operator.

Now, another choice may be emerging. Giving new meaning to the phrase "plug and play," a big Midwestern utility is joining with a start-up to offer high-speed Internet access over power lines. The service promises lower prices and more convenience: Consumers can tap into the Internet anywhere they have an electrical outlet in their house.

The new service, announced Tuesday, comes from Cinergy Corp., a Cincinnati-based utility, and Current Communications, a private company controlled by the Berkman family, which made millions on wireless ventures and counts John Malone's Liberty Media Corp. as an investor. All told, the three are putting $70 million into the venture.

The idea of using power lines to send Internet signals to homes has been around for years. It is based on the fact that electricity travels at a far lower frequency than the Internet signal, so the two generally don't interfere. But earlier efforts were disappointments, mostly due to the cost of the equipment needed and technical issues.

Two years ago, a pivotal breakthrough occurred when the industry improved the speed and lowered the price of the modem that plugs into wall sockets to bring the Internet into the home, thanks to advances in semiconductor chips.

The new modem is based on an industry standard called HomePlug, and costs about $30 wholesale. Cinergy will be handing out the modems to customers free of charge. "The modem being there is what drove us to launch this business," says William Berkman, co-founder of Current Communications.

Another technical issue has been how to get the Internet signal through the transformers that step the power down from medium voltage, which runs along the street, to low voltage, which goes into homes. Current Communications says it has solved that problem with a "bridge" that skips the transformer, allowing the signal to go through uninterrupted. It won't say what the

bridge costs.

Top officials at the Federal Communications Commission support such power-line services because they could expand the availability of high-speed, or broadband, Internet access and give consumers more choice of providers, perhaps lowering prices. Last month the agency issued proposed rules for broadband over power lines.

"Is the technology ready for prime time? The answer is yes," says Ed Thomas, the FCC's chief engineer. "The second part of the question is, is the business ready for prime time? The answer is you have to wait and see."

The issue is whether customers will sign up for the service, either by stepping up from dial-up connections or switching from DSL or cable. On the positive side, the power line service is easy to use -- plug in the modem and run a wire to your computer and you're online. But there has been little switching by consumers so far from one broadband service to another, and the growth of broadband has been slowing.

Matt Davis, an analyst with Yankee Group, a Boston-based technology consulting firm, says power-line broadband services lack key features of cable and DSL offerings, such as bundled packages of phone, TV and Internet access. He adds that more than 80% of American households can get high-speed access and that figure will rise to 90% in the next few years. "People continue to say that broadband is unavailable in a lot of places, but that's just not true," Mr. Davis says.

Mr. Berkman says his group has already had discussions about bundling its services, and plans to offer Internet phone service and either video on demand or videogames by the third quarter of this year. He adds that in many places that theoretically can get high-speed access the quality is poor. Cinergy and Current, which tested their offering on 100 homes in the Cincinnati area, say they will target areas where broadband connections are spotty and hope to sign up 20% of homes they pass.

GETTING CONNECTED

Cable modems dominate high-speed Internet access, but some utility companies hope to break into the market by providing broadband connections over their power lines.

Average Cost per Month U.S. Subscribers
(in millions) Growth 2004
(estimate) Pros and Cons
Cable $35-40 15.7 29% Fastest but most expensive
DSL $30-35 6.6 41% Slower but cheaper, especially when bundled with phone services
Power Lines $30-40 N.A. N.A. Fastest for the price, can connect anywhere there's a plug; service is unproven in wide use.
Dial-Up $15-22 39.5 -9% Cheap, but slow and not always on.

Sources: Morgan Stanley; Current Communications

In addition, the partners say they believe they have some cost advantages over DSL service and cable modems, in part because they don't have to send a technician to a customer's house to start service. Instead, customers are simply given the modems, which look like big cellphone chargers. If customers want to work in another room, they plug the adapter into an outlet there. Wireless adapters that broadcast a Wi-Fi signal are also available.

"Now it's up to us to prove the economics," Mr. Berkman says.

This effort appears to be the largest rollout of such power communications to date. Cinergy will start with two neighborhoods in the Cincinnati area and hopes to offer the service to 60,000 of its 1.5 million electricity customers by the end of the year.

The two companies have a second venture to bring high-speed Internet access to 24 million customers elsewhere served by smaller municipal and cooperatively owned power companies, often in rural areas where cable and DSL are not available.

The executives say their service will beat high-speed cable and phone connections on price, convenience and speed. Current and Cinergy plan to sell their service for $29.95 to $39.95 a month, depending on the connection speed. Cable connections typically go for $35 to $40 a month, while DSL lines are $30 to $35, with discounts for bundled services. Most dial-up connections range from $15 to $22 a month.

"We believe we are now the last-mile solution," says Bill Grealis, executive vice president of Cinergy and president of Cinergy Broadband Inc., speaking of the issue of getting high-speed lines to homes. "We are cheaper and faster than DSL or cable."

Several other companies also are in trials of power-line Internet service involving dozens to hundreds of homes and hope to begin commercial service in the next year. The systems have an added benefit for utilities: They can alert them to power outages by monitoring the lines, and can read electric meters automatically and let the utilities manage the use of power during peak demand periods.

These power-line services, if they take off, could be a boon to Internet service providers such as EarthLink Inc. and long-distance companies such as AT&T Corp., both of which are desperate to get direct connections into consumers' homes rather than relying on lines owned by local-phone or cable companies. AT&T demonstrated a voice-over-Internet phone service using power lines at an analysts meeting last week.

This is the second effort by the Berkman family, which made millions as an early investor in cellphone systems, to provide an alternate broadband service. The family, led by Myles Berkman and two sons, William and David, started Teligent Inc., a once high-flying company that hoped to use high-speed wireless connections to provide broadband services to businesses.

The family sold its stake in Teligent as part of a deal to sell its company, the Associated Group, to Mr. Malone's Liberty Media for $3 billion in 1999. Teligent collapsed two years later after it tried to expand too quickly.

With that in mind, Mr. Berkman has focused on keeping costs low and will roll out the power-line service slowly. "Looking at the lessons we learned in the whole telecom boom and bust, we have to be conservative and drive the cash flow," he says of the investment. "We don't do this often, we do this every five or 10 years."

==========
Wonder if there are any radio amateurs (hams) in the Cincinetti area where
the system was 'tested'
And if so ,whether they have reported any interference resulting from BPL. I
am sure ARRL will be happy to hear from them.

Let's wait and see.

Here in the UK ,it has gone quiet re PLT = Power Line Transmission (BPL).
In rural areas where telephone exhanges have not as yet been prepared for
ADSL ,people can register their interest in ADSL on the Web.
As soon as a trigger level ,set by British Telecom, has been reached ,
broadband facilities will be installed.
In my telephone area (covering a maximum of 1000 phone connections) the
trigger level is 150 ,whereas to date only 51 have
registered.....So I might enjoy broadband comms during 'after
life' ;)).
However the 'absence of PLT ' (a blessing) will most definitely make me
stick with ham radio.

800MHz? That's one question you'll miss...

They'll both be line-of-sight, 900MHz will theoretically have a bit more absorbtion by the vegatation and the circuit will be touchier, but 900MHz is less used -- the ARRL will thank you for populating the band better, and the 70cm crowd will thank you for not adding to the band congestion.

If you can design transmitters you should be taking the Extra. 5WPM is a joke to learn, too. My kid is studying for the tech, since the speed requirement is so absurdly low I'm thinking of upgrading to Extra myself.

most newer generation ELT devices are on 406.028, so using 70cm is probably better for longer range, not as much line of site. another thing to realize is what mode you will be using , im guessing some type of FSK.

for what you lack on transmit power, a better designed antenna system and ground tracking receivers wll make up the difference .in range for you

i know you want to build it yourslef, but ou might want to check out ramsey electronics website. they sell 433 and 916MC transmitters and recievers. i have used them in model rockets (433) and they worked great up to about 2000 feet high. i used a 70cm ht with a small beam. to track it.

Hello everybody,

I would like to design a VCO able to cover from 1240 and up to 1300 MHz in a PLL system.
This will be part of the 23cm transceiver project.

I've seen that Maxim has the MAX2754, intended for 1.2GHz operation. The datasheet shows it can reach 1300MHz.
Has anybody experienced this component in PLL at such frequencies ?

Otherwise, do you have some schematic examples to suggest with transistor but without PCB coils

Regards

Hello,

I have a project that requires more than 10 headsets that get lots of rough uses.

I have looked at using multimedia headsets as a cheap source. But worry about impedance matching and making a remote PTT for them. This is all for GMRS radios (several brands)using the common mono 1/8 speaker mono 3/32 mic connector.

I have made an experimental box with two stereo 1/8 jacks that just carry the speakers straight thru and use a simple push button for the mic's PTT. But get a load "spisszt" just as I press the button.

There is a cheap technique for making your own that I have used. A regular
plastic soda straw fits closely around a 1/4" shaft. Either glue or clamp it
onto the shaft and have the rest of the straw filled with epoxy or a glued
in wooden dowel to the length you need . Makes a nice insulated shaft
extension.

There are certainly high voltages present inside the tuner when you're
transmitting. I would not ever touch the tuner components or wiring,
with fingers or tools, when transmitting. The _most_ I might to,
would be to transmit at low power into a dummy load, and tap various
components with a long well-insulated stick of some sort, to see if
the SWR jumped around... and if I were doing this I'd certainly apply
standard high-voltage precautions (wear insulated shoes, hold stick in
one hand and keep other hand in back pocket).

As to RF coming out with the cover off - I've always heard that a
well-designed-and-constructed tuner will not radiate a significant
amount of RF even if the case is not a shielded one. Cebik, for
example, writes that "Well-wired ATUs do not radiate, consisting of
passive components only, so a metal case is not required" and
constructed an L-C-L tuner with a case made out of plexiglass.

"Aluminum L-stock pieces around the case perimeter link the sides and
bottom of the case, with an independent top piece of plexiglass and a
rim of L-stock to hold it in place. Vertical L-stock at the corners is
electrically connected to the grounded chassis rails. Only the top
perimeter pieces float, but have shown no detectable RF, either to my
finger tips or by detuning the circuit from semi-assembled settings."

I guess we each have our own definition of "significant". Get a small fluorescent tube. Hold it near one end and wave the other near the tuner coil. Depending on your power level, tuner setting, and antenna impedance, the result might spur you to think about the meaning of "significant".

OK Hams in Cincy. When you can't hear anything because the band is full
of BPL crap fire up your linears and rotate your beams toward the noise,
then call CQ all night. The BPL people will find their internet not
working because of the 'QRM' and there ain't a thing they can legally do
about it! When the customers demand their money back maybe the power

companies will call the experiment a failure.

Yeah, but...

Remember, this is a country where the majority
rules, and laws can be changed. Hams are a
minority.

This is a very serious issue, and could spell the
end of our hobby. I sincerely hope not.

when I lived in Reno, NV there was a person who was not very friendly on the radio. He was always getting drunk and once he was full of liquid courage, would swear, throw dead carriers, drive the drivers and us locals crazy. So a cb/ham operator made a device that was real small,,,it was placed in close proximity to his house, within 1/4 mile. When he would key up on ch-19, it would start a audio carrier that was intermittant,,it was like a pulse for 5-7 minutes, he would key up again and once again get this pulsating tone, is the best way to describe it. Needless to say he cleaned up his act, and started to come around. So now I am in willamette valley and have the same problem. the person who made that "toy" has passed on,so now I am looking to get something of the same concept made. Any ideas? JPT.

I've used these with success with HF gear. (TS-940, IC-765, FT-1000MP)

They require DC bias on the mike element. The HF gear has a source of
+8 or +9V DC on the mike jack - I connect that to the tip of the mike
jack through a 10-20K resistor, then tap the audio from the same point
using a 1uF tantalum blocking capacitor. Works great.

Of course the headphone part works fine without modification.

Finding the DC biasing voltage on the GMRS radios might be a problem.

I guess I always get confused by these posts. What good does it do to jam the offenders receiver? He can't hear it until he unkeys. If he keeps getting that annoying tone in his receiver, the easiest way to get rid of it is to go key down again.

Hi,

The way I read the post is that the pulsing noise would
come out of the rig of the offending individual each time
he keyed-up which puts this 'device' in the urban-legend
category.

Cheers - Joe

1747. Re: 455 KC oscillator = CB jamming device

Source record: 28134

Hi,

OOPS! On a second reading I think that I misunderstood the posting and realise now that the device was meant to generate an annoying signal for a few minutes 'after' he had released the pressel. Were it close enough to the offending station, it would only need to be of quite low power and limited sensitivity so restricting it to the offending individual.

As we all know, one of the intentions of those who seek to disrupt a channel is to subsequently wallow in the result of their efforts. This signal then would help prevent them from enjoying the fruit of their labours. Unfortunately though there doesn't appear to be a newsgroup equivalent.

Cheers - Joe

That's what I got. To do this @ 455KHz would require lots of antenna
or power. 1/2 mile is very long. I used to interfere with other kids
transistor radios by tuning mine 455 away so that the LO in mine was on
their Rx freq. weeeeoooeeee. Only works a few feet.

Is www.mailman.net down ?

I've not had an e-mail from any of the Mailing lists I'm subscribed to
with mailman.net (qsl.net's list server) for about 48 hours.
Specifically

QRP-L, ELECRAFT or HAM-PIC

I have been getting stuff from Yahoo's GQRP Mailing list and from
Yahoo's PICLIST without problem.

I'm interested in identifying the Elementary Electronics Magazine issue that contains the One Tube Superhet project. It is from about 1970. I built this project, back then, and still have the radio but not the magazine. I have salvaged a few parts over the years for other projects but bringing it back to it's former glory will be easy. Thank you, doug

As others have commented, its possibly a 1N4148, its easy to read a 8
for an B, and with small computer text/print the 0 when you use the
European? version can be mistaken for a 0 a B or an 8.

Hi all,

I need a simple design for a BPF with a centre frequency of 17.2Mhz.,
corner frequencies one Meg or therabouts either side of that and a
reasonably good shape factor (nothing critical here). I don't mind
having to do a bit of tweaking of values myself if anyone has
something close to that they can post. Passive L/C combinations only,
please. (assume the usual 50R nominal Zs.)
Thanks,

p.

I don't really have access to all the radios to do some hunting and
modifying to each. So it would seem a bias circuit using a battery in
the PTT box is in order. That is if getting rid of this minor
distortion is worth the effort. Something like a .5 uf cap between
the switch and the mic element with a 1K resistor and a single AA
going to ground? Sound about right?

[snip]

Such a design can be achieved with a vert simple formula and a pocket calculator or slide rule. Why don't you just use Bennett's simple formula for the maximally flat approximation all pole element values, or Takashi's simple formulae for the equiripple approximation all pole element values?

Oh... perhaps you want elliptic [Cauer or Darlington] designs or perhaps a completely general parameter design in that case ypu will need a computer and will need to do some programming or buy some programming, or better yet...

Hire a consultant... :-)

Hey, I've designed literally thousands of LC filters over decades in most frequency ranges, for clients who have paid me well. I have access to very sophisticated and comprehensive general parameter LC filter design programs that I have written [In Fortran BTW] over lo these many years and they are immediately at my disposal.

But... unfortunately for some... I never design filters for free!

I'll do it for you at my usual consulting rates.

My rates are reasonable. Just call or email me to discuss the terms and conditions.

:-)

Conversely, go to the WB6BLD website and download the free student version
of Elsie and do it yourself, will take an hour to learn the software and 5
minutes to design the filter. Another good filter program that is free and
available and relatively easy to use is at the AADE website.

Would be worth your while to learn even if you seldom design a filter.

The usual technique is to get a book that has tables of normalized LC
lowpass filters of various types, pick a response you like, and scale
it and map to a bandpass. Williams' "Electronic Filter Design
Handbook" has all this stuff.

It's mildly tedious, so I won't offer to do one for you.

John

A friend of mine was thinking of building a small transmitter that would
put out on 262khz, 455khz (am) and 10.7mhz fm. It was to be a low power
portable transmitter to be used mobile when he got cut off my some
***hole on the road. He could then curse the guy out over his radio
(assuming he had the radio on).

Try this 5 pole Chebychev with 0.1dB ripple

Fc=17.2MHz BW=1MHz

CAP 1 2 C=27PF
PLC 2 0 L=1uH C=56PF
CAP 2 3 C=4PF
PLC 3 0 L=.1uH C=80PF
CAP 3 4 C=3PF
PLC 4 0 L=1uH C=80PF
CAP 4 5 C=3PF
PLC 5 0 L=1uH C=80PF
CAP 5 6 C=4PF
PLC 6 0 L=1uH C=56PF
CAP 6 7 C=27PF

Lots of books out there with normalized tables. Go to a technical university library and spend a few hours pouring thru some filter books. You can use Linear Technology's FilterCad to see what sort of filter type and order you need. Then hit the tables and make an LC filter. The best book I have found is "Simplified Modern Filter Design" by Philip Geffe, circa 1963. You can sometimes find this book in a university technical library. It has an excellent treatment of basic filter design and how to go from a low-pass prototype to other filter types.

For your particular filter, you might consider a loose-coupled design, also called coupled resonators. Good for Q > 10. Your design will just fit into this category if you don't mind some imperfection. This type of design produces nice component values. "Electronic Filter Design Handbook", by Arthur Williams and Fred Taylor (ISBN 0-07-070434-1), page 5-19 has info.

Mike, I have seen your test posting to HAM-PIC, but am also
experiencing no messages from QRP-L. The last one of these I have is
digest number 3211 from 2/28/04.

Download the freeware filter design software from

http://www.nuhertz.com/

Their UI is, uh, colorful, but it seems to work. Pay attention to the source and load impedance. Also, it doesn't like 'engineering' notation (eg: 17.2Meg), so use scientific notation like 17.2e6 instead.

The freeware only designs filters to 3rd order, so if you need better than that, either dig it out of a book or buy the software. However, it does both passive and active filters. Its a bargain at twice the price... ;)

Regards,
Bob Monsen

If you get QEX, the latest issue has a DDS/PLL board that might suit you
Alternatively, see http://www.qsl.net/ke5fx/synth.html
for details
Instead of the Minicircuits ROS 2100VW specified, use a ROS 1410 or ROS
1500. Are far as I am aware, they are pin compatible. You would need to
make some adjustments to the loop filter values and supply volts etc.

Download RFSim99 and let it do it for you. Download Filter Design
from AADE's site and let it do it for you. Download NuHertz's demo
version of their filter design software and let it do it for you.
There may even be web aplets that will do it for you. And then you
can play with configurations and shape factors and the inevitable
tradeoffs between complexity and shape factor.

Cheers,
Tom

Pulling this thread a little to one side:

The "Radiotron Designer's Handbook" from the Amalgamated Wireless Valve Company (Australia) had a number of tricks to reduce the tube count in radios. Its main interests are AM and shortwave broadcast radios.

The book was sold by RCA in the USA. Anyone interested in tube radios should have a copy. It's a couple of inches thick. It was last issued in the 1950s - mine includes info on FM broadcast receivers.

Richard,

I had the idea, but minicircuits ROSxxxx are quite expensive here in France.
more than 40 euros each.
I've found a schematic for a VCO covering 1050 to 1350 MHz, quite simple,
without PCB coils. Cost should be less than 2 or 3 euros.
I'll try to design something upon this base.

Sure - the whole thing would cost several hundred Euros I would guess.
Phase noise would not be ideal as the VCO is covering 500 MHz when you
only need 70 MHz
Still, I suspect VCO design even for a narrow bandwidth is not for the
fainthearted....

Only two? I thought you could pick anything between about 600 and 2000
depending on whether you wanted leather seats, the high end stereo, etc.

The base rig on the order page is 599, I assume that's authoritative. Looks
like you're in for a grand for a reasonably decked-out, QRP CW rig.
Expensive compared to your typical rice box, but cheap compared to anything
with a similar receiver.

From: St&#65533;phane Rey <sre_prolem@yahoo.com>
Message-ID: <c2a4koht1@rex.ip-plus.net>
Source record: 28077

I've already designed some VCO but at lower frequencies.
This will be my first design above 1GHz.

This VCO will be the base for a 1240-1300MHz Narrow Band FM transceiver. I'm going to include it in a PLL system based on the LMX2326 National Semiconductor PLL chip.

Concerning DDS, I'm designing an hybrid DDS/PLL for 144MHz. In fact it should be usable for any frequency.
I would like to design a SSB transceiver. Once again, I've never tried SSB demodulation above HF bands

Ham-radio is experimentation so... I will experiment.

Thanks for your comments Richard

Best regards
Stephane

My reaction (below) to the "QRM solution" (quoted above) was previously posted on QRZ.net.

This is not a suggested course of action.

The power companies know all about the Part 15 rules. They will never attempt to prosecute you or harass you via the FCC or Federal Courts.

You WILL find yourself in a LOCAL court room, before a LOCAL judge, and a LOCAL District Attorney. You will be prosecuted as a ï¿½Public Nuisance" under the same laws used to protect the public from dogs running at large, kids who squeel their car tires, and people who leave piles of garbage laying about.

The judge will likely issue a "cease and desist" order. If you ignore it, and fire up your rig anew, the LOCAL sherriff will be ordered to take possesion of your equipment and probably take down your antennas (at your expence), as well.

You can appeal these actions ... and you will very likely win your case on appeal. But, only after two or more years of gut wrenching legalistics and an expenditure reaching the $100,000 range ... probably several hunderd thousand dollars. Each and every ham like you, will likely have to fight this same battle, over, and over again ... for himself, by himself, in each and every jurisdiction. The ARRL doesn't have the money or staff to help you.

If you think its not possible, ask the guys from New York, who were prosecuted under the "scanner laws", if their rigs have been returned to them, yet. They won their cases.

You're going to get BPL, in one form or another. The reasons have nothing to do with an advance in technology. They have everything to do with MONEY and POLITICS. You're going to get BPL. And, quite frankly, you deserve it.

The FCC, The US Congress, The US Court systems ... are the very best that MONEY can buy. The Commissioners of the FCC are NOT technologists ... they are bookkeepres, accountants, would-be/failed politicians (or, their sons, daughters, brothers, and sisters), and lobbyists. They are

NOT your "friends-in-high-places". They've been bought and paid for. They "take the king's coin, and do his bidding".

Why? You, Amateur Radio as a group, are mostly old, mostly fat, selfish, lazy ....and, you don't VOTE regularly and knowledgeably. When you do vote, it is on issues having little to do with your own self interest, your community, or your hobby.

At present, the FCC records some 900,000 licences for the Amateur service. Of these, at least 15% are dead people. That leaves about 800,000 "living" hams. Of those, less than 20 % vote regularly. So, you have a total influence with the US Congress of aproximately 160,000 votes .... scattered across 450 odd districts. Not much for political "Clout".

You are selfish. Your promote your hobby as an exclusionary fraternity. You are NOT, at this date, an inclusive, accepting, welcoming union of like minded and interested individuals. Rather, you link your hobby to additional exclusionary protocols ... religious belief (I throw "morse" and Christianity in the same pot), sexual orientation (or just gender), language, race, and social origin. If you doubt me, you haven't been listening to much of the chatter on 20 and 75 meter SSB. On my local 2 meter repeater, there are "extras" who won't even chat with a "no-code tech" or "queer CB'er". Heaven help you if they hear you practicing your Spanish with someone from Cuba.

What the hobby needs to force a repeal/reconsideration of BPL is an infussion of about 10 million kids each of whom has 2 parents and 4 grand-parents ... all of voting age. 60 million votes ... thats CLOUT!

But, given the history of such things as 'Incentive Licensing", the "Save Eleven" fiasco, and the religious "Rite of Morse", there is little chance of seeing any such infusion before the entire hobby is history.

You are going to get BPL!

In short, don't invest in a new Icom rig, or that fantastiic Orion. Instead, buy fishing gear ... find a new hobby, 'cuz this one is all but dead.

Fair point. I just wondered if anyone had a design similar to
requirements *already* lying around they might post it, that's all.
Save me a bit of scrawling and button-pushing. I didn't wish to put
anyone out.
Thanks to all who responded, BTW. Some very useful steers.

Hi,

Can any one help me with an application note or circuit for a 2.4GHz
PLL circuit using a HiMARK DM1461 PLL chip ?

I'm hoping to modify a handheld 2.4GHz Video RX for continuous tuning
but I can't find info on the HiMARK website.

The PLL uses two varicap diodes in some sort of push push arrangement
driven directly from the PLL chip.

I've not seen anything like this before, so I'm looking for some info.

I only find one price: $599.00

That's for the bare-bones K2 (CW only, 80/40/30/20/17/12/15/10 meters, 15 watts max) with no options, and less shipping and tax (if applicable).

Options include (this may not be a complete list - they keep adding goodies!)

- Noise blanker
- SSB adapter
- 160 meters/2nd rx antenna
- QRP ATU
- Analog audio filter/real time clock
- DSP audio filter/real time clock
- Internal battery
- Serial link
- 100 watt internal power amp/serial link
- 100 watt ATU (mounts externally)
- External band interface box

And lots more.

What prices do you see?

The simplest filter that'll get you by, is this one. (a couple of tuned
circuits with a bit of top-coupling :-) ...

___ ||C1
-|_R_------.----.-------||-------.----.-------, O/p
Source |L2 |C2 || |C2 |L2 |
I/p | | | | .-.
C| --- --- C| | |load R
C| --- --- C| |R|
C| | | C| '-'
| | | | |
=== === === === ===
GND GND GND GND GND

F1=16.2e6 'lower limit MHz
F2=18.2e6 'upper limit MHz
R=50 'Ohms source and load impedance
Pi=3.142

C1 = (F1+F2) / (4 x Pi x F1 x F2 x R)
C2 = F1 /(Pi x F2 x (F2-F1) x R)/2
L2 = 2xR /(4 x Pi) x (1/F1 - 1/F2)

The inductors end up being quite small but a couple of loops of wire cost
nothing. At 25megs the output is down to about 3% , which is not bad.

This particular style is the "3 element" design and from the traditional
"Constant K" filter stable. The pleasantly simple to design "constant K's"

and associated "M derived" filters, can be easily and freely used for most day-to-day electronics work.

Exact Filter design, or 'synthesis' as they nowadays prefer to call it, can be a nightmare if you're coming in from scratch. Even using a filter design programme requires a good knowledge of filter types/performance/spec's before data can begin to be entered.
If not using a prog' you move onto the more vexing method of having to design an initial (prototype) low-pass filter, either via precalculated tables or computing the required co-efficients, then mathematically transforming the low-pass values into a bandpass (etc) design. For higher order filters it can be ball-acheing drudgery and even then inductor resistance has a nasty habit of spoiling that pristine work of art. (not a problem with DSP filters).

I can't suggest a decent book, as the general purpose books seem over complicated and destined to be written by maths people for maths people. (The old GPO line-comm's manuals have useful notes on the 'K and M ' filters).
regards
john

I'd suggest Temes and LaPatra, "Circuit Synthesis and Design." Now out of print, but occasionally you can find a cheap old copy used.

I'd also suggest the original poster does a couple of the exercises (he might have already), doing what you describe with building a low frequency prototype filter and then transforming it to a different type and frequency range, but just for, e.g., a second order filter. There's not much to be gained by doing the 'drudgery,' as you say, for a higher order filter other than proficiency in aithrmetic.

Jamming the (hip-hop/rap crap)assholes with their high powered car radios blasting that hip-hop crap is EASY! try this...(I do it a lot) take two transmitters(I use 2 50 watt 2 meter TX's) and key them both at the same time. Set the frequency to something not used a lot (I use 146.565).The resulting hetrodyne will come out of ANYTHING non-linear! It tears their system a new asshole.If one of the radios is VFO (like my IC-706MKII-G) you can swing it around and set it for the most annoying tone.
It usually hits their power amplifier directly, they dont have control of it from the head.In fact when we tested it on a guys system(he was a willing sucker) it got worse as he turned down the volume!! Seems it forms a ground loop and the RF gets into the power amp even better. By the time they figure it out, damage is done. a pair of 2 meter "spikes" is hard to see and they dont know what they are for...have fun! Eddie

Or, you can ask me for a free package of LCie4 that I first wrote back in '93 and have revised only slightly since then. DOS level, no fancy screens or prettyness in graphics...but LCie4 allows individual component value variations, actual unloaded Q values, and Sensitivity (output response or input impedance) to any specified tolerance of all-Cs or all-Ls. Works under Win98 and WinXP.

Does 3 to 9 section Lowpass, Highpass, Bandpass, and Bandstop and 2 to 9 section "resonator" Bandpass filters with choice of "high" or "low" impedance coupling by C or L. Butterworth, Tchebyshev (or Chebyshev, heh heh), or one kind of Elliptic, choice of minimum L or minimum C configurations on odd sections (or 'orders' as some insist on calling them).

Output Response and Input Impedance are separate analyses, not part of the calculation of filter component Synthesis. Q of all Cs or all Ls is frequency-independent; i.e., same specified value at all frequencies of analysis. That's a compromise to simplify analysis; purists want a SPICE-like thing, no doubt, where they can model everything...:-) Chances are those purists never built a real one to experience the joy of transmutation of paper into hardware.

A "parts listing" command yields a half-S version of a "schematic" good enough to show the values of separate components, on-screen or on paper. LCie4 is fast and thorough, lets one play with values and affect on response until one gets tired of doing so. :-)

Less than 250K in total package size, sent as an e-mail attachment in response to polite e-mail inquiry. It's free...do not ask for money back if dissatisfied...

Since your too lazy to do this, here, have a few designs. You can run
these on LTSpice. What is reasonably good shape factor?

hello all,

i have a vfo from a heathkit hw-101. i also have a knight kit t-60.
question is what would it take and how much trouble would it be to build an
external vfo for my t-60 transmitter using this vfo? i have read some of the
old hanbooks but wanted to hear from the group.

tnx and 73 mike

Hello Paul,

I'm not in the habit of fishing for compliments but, out of curiosity, did you find my program BANDPAS1 of more use to you than the many other responses to your query.

By the way, the Pi-network filter can be matched to ANY pair of terminating impedances by tapping down the coils at each end. Been there - done that. It also allows the most convenient component values to be used.

Absolutely not. In a homodyne receiver, it's only necessary to recover
the carrier by way of a limiting amplifier.

>

What's being suggested here is a synchrodyne receiver, where an
oscillator is locked to the carrier of the incoming signal. This requires a
Costas loop and is not at all necessary for simple AM detection. A homodyne
is sufficient.

Indeed. Legendary Reg's programs are always well worth a look at, of
course. I did try out his filter design one last night, just out of
curiosity. Looks pretty neat. I'll run some sims through it later to
see what sort of results it gives. Might post the results later if
time permits...

I don't think it's a good choice.

The vfo from the SSB transceiver has a fixed range, I believe 5 to 5.5MHz,
and must have been linearized so the dial comes up properly.

The T60, or any AM/CW transmitter of that vintage uses a 3.5MHz or
7MHz (and that might change with the band) and multiplies up for the higher
bands.

In order to use the first with the second, you'll have to shift the
VFO down in frequency, likely by changing the coil. You'll kill
the linear tuning, and unless you do a good job, you may mess with
the stability. If the dial is still attached to the VFO, you will no
longer have the proper display of frequency.

The best way, though not the simplest, would be to feed the VFO into
a mixer, and then feed a crystal oscillator output into the other port
of the mixer. The output of the mixer will be the 3.5MHz or 7MHz that
the T60 needs, and the frequency readout of the VFO will remain true.
Tradeoffs are that if you don't put a good filter on the output of the mixer,
you will get spurious signals, and while the readout will remain accurate,
it will not show the actual frequency, since the T60 will be multiplying
it's output frequency. On the higher bands, as multiplication goes up,
the actual band will be covered by a smaller swing of the dial, though
that applies to any VFO used with a multiplying transmitter.

> I like to experiment with the Analog Devices DDS for a receiver.
> Anyone have a favorite one with good features and least hassle?

Well, it all depends on what sort of design you are doing.

If you're working on a very low power portable design, you want to look at the AD9834. This baby consumes a mere 8ma at 2.5 to 5 volts. The reference clock is limited to 50 MHz, which means that 20 MHz output is about its limit with reasonable spectral purity, though you might get up to the 15 meter band with careful filtering.

The AD9850 and AD9851 are popular for a lot of ham designs. The AD9850 has a maximum reference clock of 125 MHz, so it's good through the 6 meter band; the AD9851 can handle a reference clock of up to 180 MHz. These chips consume around 100ma at 5 volts (somewhat less if run at 3.3 volts, but then the reference clock speed limit is lower); not ideal for a battery powered design, but still reasonable. The New Jersey QRP Club offers a small daughterboard designed for the AD9850, and there is lots of code available online to control them.

The AD9950 series is the new kid on the block. These run at 400 MHz, making operation up to the 2 meter band feasible. They have a 14-bit DAC, rather than the 10-bit one used in the older devices, so spectral purity should be significantly improved. They consume about 85ma; reasonable for this level of performance. There are some drawbacks... they come in a tiny package that's hard to solder by hand. They run at 1.8v, and the inputs only accept voltages up to 3.3v, so you'll want to design with lower voltage control logic. Still, if you want to push the state of the DDS art, these are your chips.

I haven't heard of any ham experimentation with the AD9858. This one can take a reference clock up to 1 GHz, which means that 450 MHz output might be possible with careful design. It's power-hungry, though; around 750mA.

You will also see some designs using older chips. The AD9830, the first readily available DDS chip that could handle a 50 MHz reference clock, and its serial input cousin the AD9835, were popular for a while, but the much lower power AD9834 is more appealing for new designs unless you need very fast frequency changes (the serial input lowers the possible rate of change). The AD9852 and AD9854 have seen some experimentation, but these chips are power hogs (they can consume more than an amp of power!), so they are definitely out of the question for portable designs, and it's hard to see a reason for using one of these in most designs rather than the AD9950 series. The AD9854 does have the unique feature of having TWO

synthesizers on the same chip, which could be useful for people
experimenting with high-speed digital data modes.

The FCC regulations do require us to use the minimum amount of power to
get the job done. Is trying to overcome QRN a good reason to switch to
high power? I think the FCC regs would support that. I'm sure that if
we just operate as we normally do, perhaps switch to high power if
necessary (but still remain within the law as far as all requirements
apply) we are not anymore a Public Nuisance than we ever were. It's
like the guy who moved next door to an airport and then complains about
the noise. He KNEW the airport was there. Same here, the BPL providers
KNEW about part 15, they just have to live with it.

As for the rest of your comments, I suppose you have made up your mind
and have burned your license, framed the ashes, and sold your radio gear
to the CB'er next door. I think there IS hope for the hobby, attitudes
about Morse are changing, the old farts in the ARRL being replaced by
younger blood. I personally think SOME way of keeping CW from totally
disapearing is needed, just to keep the diversity alive. It IS time for
a CW free HF license with mainline privilages. Keep the Extra class cw
bands exclusive, we can afford setting aside 25khz on several bands for
this. Keep some segments of all bands reserved for CW and other 'narrow
bandwith' modes, according to their usage. The ARRL's new band plans at
least sound like a start toward making ham radio more accessable to
everyone. BUT some sort of work IS needed to get a license, or we will
be left with nothing but the kaos that CB became. (If you don't put
some effort into getting yourself license, will you have enough pride in
it to respect it?)

As for BPL, I think in a decade it will be nothing but a memory, killed
off by better technology. Some of the power companies that are getting
into the broadband business are doing so by opening up their own
networks (which are fiber and rf based) to their end customers. The
term BPL in this case refers NOT to the method of delivery, but to the
provider. The power companies use a network to control power loading
transfering data between distribution points.

I think you missed the point of his post. It is an editorial on the state of the hobby and I think it drives home the current attitudes many (no all, of course) hams have towards the proposed changes the ARRL are supporting. It's really human nature; many people are resistant to change for variety of reasons and sometimes it takes a long, hard look in the mirror to see how silly this resistance is. The point being, if one insists on "living in the past", then their is no future. This applies to everything, not just amateur radio.

And I don't think the original poster has burned his license. He's probably doing more than you or I to save the hobby by shoving the egocentrism that many hams exhibit right back in their face. And for the record, I don't think the ARRL went far enough in their recommendations. I believe their should only be two licenses: a beginners with VHF/UHF access and limited HF access, and a "general" license with full privileges and no CW required. Before you (or anybody else) flame me for this, note that I do know CW. The only reason I learned it was to get HF privileges. I maybe had 3 or 4 QSOs using CW but it's not for me. I find other digital modes like PSK31 to be more fun. But that's just me.

Wouldn't it be easy to point at the back of one of the part 15 devices and show the judge where it says the device must not cause any interfearance to licensed devices and must accept any interferance from the licened devices ? Then counter sue the power company for interferance and being a public nuisance to you.

1826. Re: 455 KC oscillator = CB jamming device

try taking a look at the ubiquitous 555 timer chip - one could rig the thing so that it would key up a radio upon recieving a carrier that was above a certain level - something like taking the signal from the s-meter and using it for a trigger signal works real well, and ensures that only the local area gets qrmed. naturally, the interval it keys up for is up to the builder, with the 555. Another interesting thing is , that if this is placed real close to the guy's house, very little power will be needed to operate it. a motorcycle battery would last a long time at a 100 milliwatt level..... and if close enough, would give him 20-over s-9. Think i remember someone doing this once, but cant remember just who it was... <G>

Has anyone tried hand soldering leads on a QFN package? perhaps dead-bug style using wrap wire? Or?

I have 20 or 32 pin QFN chips I'd like to play with but the tiny size is rather intimidating. I have successfully soldered SSOPs.

thanks, Tom

============================

Unfortunately, only about 5 percent of the 'information' published on this and other newsgroups is of any use. Much of the remainder is misleading. And the most serious of the problems is most folks' inability to distinguish between wheat and chaff.

Many who are satisfied and immediately say thank you are too hasty, later finding it won't work. Too much of the information falls into the category of old wive's tales. If it sounds OK then it must be right!

The frequency of arguments between 'experts' gives the show away.

But most of you know this anyway. So why do I bother to say so?

Entertainment value is another matter. It stimulates the mind. Hence the group's popularity.

Reg.

Best way that works for me is using a hot plate to heat up the pcb to 170C.
then apply a drop of flux on the bottom of the chip, melt solder on the pcb
footprint and place to chip down. capillary action will direct the chip in
place.

Catch this senario:

You and your lawyer bring the Part 15 device to the show the LOCAL (Municiple) Judge. The power company and there lawyers have assembled 200-300 of their customers in the same courtroom ... pop's and mom's, grandma's,etc. ... all LOCAL voters ... all screaming for your "blood" because have fucked up their internet access ... intentionally!

The Judge knows that his decision will likely be reversed on appeal ... but, ONLY if YOU have the resources to initiate that appeal (It'll start in the 100 Kilobuck range). The Judge also knows that the folks in the courtroom will all vote for HIM in the next election ... and the power company will also make a money contribution to his campaign.

You are living under the mistaken assumption that RIGHT (or "rights") and WRONG have anything at all to do with this situation. Its not about laws and regulations. Or, even physics. Its about MONEY. Its about POLITICS. Its about GRAFT. In short, its not going to be a fair fight.

Bend over!

And BTW ... Just keep telling me how important it is that I vote Republican in the next election (terrorism, abortion, and all that idiotic crap). AND how important it is for prospective hams to learn and love morse code.

I would almost agree with you on having 'only' two licenses. I still
like the idea of the 'EXTRA CLASS' license as a means of promoting self
improvment. It only offers a very small increase in privileges, several
small slivers of bandwidth allocated for CW (and perhaps keep the extras
phone slivers as well). But do combine the advanced and general class
band segments and open them to everyone without the need to know CW.
The CW band segments should still remain, but call them 'narrow
bandwidth' segments for use ONLY with modes requiring less than say
500hz bandwidth. This would include things like digital, PSK31, and of
course, CW (which could become a digital computer mode no longer
requiring any gray cells to perform the incoding and decoding!).
Re-evaluate how much of each band should be set aside for these narrow
bandwidth segments, perhaps.

There are many hams that love cw (and would use it even if it was NOT required) for things like QRP backpacking (these itty bitty rigs are quite popular, the kits sell like hotcakes). CW IS the ultimate weak signal mode. I do say this with second hand knowledge though, like you I havn't used CW much in years, but I wish could improve on that!
I got my Extra when they lowered the CW requirement to 5 wpm and only the written test stood in my way to get from Advanced to Extra. (The challenge of the written test was something I could handle, and it gave me a chance to bone up on theory I hadn't looked at since college.)

In closing on that, I wouldn't push CW on anybody, but I would hate to see it die out.

It does not seem to make any differance which party is in. I usually vote for someone that has never been . If you ask the 5000 people out of work in the town I live in whose cotton mill closed who they should have voted for I bet they would have said Ross Perot but it is too late now. I don't even know who or what the platform was in the last presidential election but I voted for the third party, same as the ones before that.
You are right, the judges are not elected.

Source record: 28026
Cross-posted to: sci.electronics.components,rec.radio.amateur.homebrew,sci.electronics.repair

At a hamfest I picked up a bunch of what I think are axial lead tubular metal case tantalum capacitors by Kemet. Case size B and C. I'm going to call Kemet tomorrow but in the mean time I wonder if anyone can decipher the code the capacitance and voltage.
+M 39003 01-2035 7440MB 31433 JM, it measures 70 microfarads
+M390003 01-2021 7452MD 31433 MW , it measures 17 microfards
M390003 01-K 2017 7426MA 31433 JA, it measures 33 microfarads

From the Kemet website I know that M390003 is mil-spec and the 31433 is the source code whatever that means. I think the last two letters are the date code but the 01-XXX and XXMX escape me but I'd guess it's the stuff I want to know! Any help appreciated.

"One of their lawyers"?????

The only ARRL lawyer I know of is Chris Imlay, and he has quite a few other clients as well. Perhaps they would hire a lawyer for you, but I wouldn't count on it.

1843. Using a power mosfet to select from various power sources for HF rig

1845. Re: designing a 1240-1300MHz VCO

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-08 12:22:52 UTC
From: St&#65533;phane Rey <sre_prolem@yahoo.com>
Message-ID: <c2hosgbag1@rex.ip-plus.net>
Source record: 28032

I've seen a description of a VCO able to cover from 1100 to 1315 MHz using
the MAX2754. The datasheet gives 1300MHz as maximum frequency.

I've ordered one and will test it.

Hello,
(Disclaimer - I am a novice electronics buff - just a few small projects)
I have a small keychain remote used for advancing powerpoint slides. It has an integrated laser pointer that is very useful in presenting which is why I really want to get this to work.The remote is stated to be 433 mhz. The reciever is a small box about the size of a pack of cards.
Right now it has a range of about 40 feet (the product spec says 100')
I think it may have to do with the enviroment. We use it in a church and there are several wierless mics ect.
I opened the recever and inside was a stiff wire antena bent into a square about 1.5 inchs per side. It is soldered onto the board.
So I am wondering how I can increase the range of the transmitter/recever. Can I just solder a longer antena? If possible I would like it to be somewhat omni directinal. The product spec says it is (is that why the square ant and not a long skinny one???)
Also while looking online I see places that sell 433 mhz ant's for about 15$- They are made (I think) for handheld walki-talkies(??) would somthing like this help me.

Any help would be much appreciated!
Thanx!
Keith

After several calls to the factory I was able to find someone who had a book on the codes. Here's what he gave me when he figured out what number was important.
2116 = 1uF @ 50V
2064 = 6.8uF @ 35V
2139 = 18uF @ 50V
2031 = 22 uF @ 15V
2017 = 33uF @ 10V
2004-J = 47uF @ 6V
2035 = 68uF @ 15V
2021 = 100uF @ 10V
I've measured several on two different capacitor meters and all read close to what the factory told me. I wonder why they coded the values with numbers that don't make any sense? Military intellligence?

You may be able to get the issue from QST, provided they still ahve copies, for a small fee. And unless they stopped the practice, if they no longer had the back issue they would photocopy the desired article for a small fee.

You can buy QST on a CDROM, and get 5 or 10 years of other articles at the same time.

The article, along with a second, July 1987, article from the same author on the topic, and Doug DeMaw's January 1990 about building a tester for measuring the crystals for such filters, were reprinted in the back of "W1FB's Design Notebook".

And surely the same ground, if not the exact same material, is covered in the relatively recent book from the ARRL, "Experimental Methods in RF Design". Its authors include Wes Hayward.

Greetings,
As a newbie to RF building, I have noticed that some instructions tell you how to wind the coil, and they give you the value of the coild as well...

In my scenario, the inductor in question is a .72uhy which the directions state to use 17 turns of #30 around a toroid. I don't have the requested toroid, so I was just going to wind a .72uhy inductor around a 1/2W 5M ohm resistor.

This will just the same right? Whether its a .72 on a toroid, or a .72 on a resistor... they are both the same, correct?

Thanks for your help.

There will be differences in the coil Q and sheilding (toroids are
self-shielding and often have better Q than air-wound). I don't have the
vaguest notion of what your circuit is, but you can probably get away with
it, at least until you've ordered the right coil form.

Well maybe not. They'd be the same inductance, but other factors come into
play.

What's the application? In various wideband applications, a core material
is specified to give it broadband response.

There might be a specific reason for using a toroid, because of it's
self-shielding qualities. If you're building in a small space, it may
be counting on that self-shielding.

Serious question. What does "73" mean?

I have a stack of "73"mags. I'm not a ham however.
If I was, I of course would know.

Anybody? I know it's a stupid question, but I don't know.

TIA,

Dennis

Keith,

You may be better off putting a better antenna at the receiver end. The optimum would be a 1/4 wavelength. Hey, anybody out there remember the damn equation for this... 300,000 meters per second devided by something-or-other???

A wavelength of 1 meter is a frequency of 300 MHz.

So 433 MHz will have a wavelength of (300/433) meters, or 9/13 meters.

A 1/4-wave antenna would be (1/4)*(9/13) meters long, which is 9/52
meters long -- which is just a teeny bit longer than 9/54 meters,
and that's 1/6 of a meter, or (1/6)* 39.37 inches, or just a smidgen
over 6.5 inches long -- and all that assumes I did the arithmetic
right. Since I'm a math jock, there's no guarantee I did, so check it
yourselves.

I just fired up the 4-banger calculator, and it tells me that the
1/4-wave antenna should be 6.819+ inches long, so 6.5 is a good
ballpark figure.

Well, Catherine is misguided. People obviously want to minimise their
effort while preserving the quality and timing of the results.

Depending on the app you might luck out but I doubt it. Order the toroid
but while you're waiting you might try increasing the number of turns.
Experiment and improvise, that makes the hooby more intersting. Also try to
read up on air inductiors and those on toriods, I assume it;s ferrite.

The American Radio Relay League published, some years back, a list of frequently-used expressions. These were numbered, so that "Best Regards; Love and Kisses" could be encoded as "73;88".

"Best Regards" (or whatever it is) just happened to be number 73 in the list.

The numbers, like 2116, are just sequencial numbers on a very large
table that covers many pages in a manual. The numbers make sense
when you have the manual.

I am trying to make the Micronaut. I have put it together manhattan style (which I find soooo much easier). I have tried using the air core and a toroid I had...
The trouble is at this point, is the thing won't oscillate. The only substitues I made was, instead of a 2n2222, i used a 2n3904... I also had to use 220pF caps instead of 270pF's for C1,C2 and C3.

I have checked w/ a freq counter, and I see no oscillation coming of of any test points.

Has anyone made this?
http://imagenisp.ca/jsm/Tuna.html

Thanks in advance.

> Serious question. What does "73" mean?
> Dennis

In olden days when sending messages via Morse code (CW) there were many messages that were the same. There were many greetings and endings which were also the same. It saved time to have a standard list of message numbers and just send the numbers.

88 = Love and Kisses

There are all kinds such as "I'm OK. Arrived safely" and the like. I have a list @home. arrl.org probably has the whole list on their web pages somewhere.

I don't know what 74 is, but my dad (W9EHS) always said "74, one better than anybody else".

Commonly used at the end of conversations between hams, roughly equivalent to "best regards." Or more informally like "Aloha" or "Caio." Abbreviations like that grew out of the desire to shorten commonly sent words and phrases when using Morse or International Code.

Cheers,
Tom

Oh boy. When circuits get that small they cease being "simple" and start getting "subtle". Every componant value makes a difference. That having been said an air-wound inductor should be OK in that circuit, because that filter isn't very high Q to start with, so a Q=50 coil won't be that different from a Q=75 coil.

In order for that circuit to oscillate the load at the crystal frequency needs to look like an inductor in parallel with a not-too-small resistance. I have _not_ run the numbers on the circuit with the values given or with your values, but decreasing the capacitance at C2 and C3 _will_ increase the amount of power that the antenna is trying to take from your oscillator, which may cause it not to start. This may be your problem.

I'd start by trying 270pF caps, or putting 47pF caps in parallel with the 220s. If that doesn't do the trick start looking for a garden-variety wiring error (I've spent days in fruitless theoretical analysis because of a cold solder joint -- it ain't fun).

Good luck.

1870. Re: What does "73" in hamspeak

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-08 23:15:25 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <104pvkib5am3d52@corp.supernews.com>
Source record: 27957

As others have mentioned, 73 means "best regards" in hamspeak.

It comes from the days of the telegraph, when a group of numbers were used as a sort of shorthand for common phrases and functions. The number 73 meant that the signature immediately followed, sort of like:

73,
Roy Lewallen, W7EL

A lot of hams like to say "73's" which of course means "best regardses", an endearing and Gollum-like affectation. These are, I suspect, the same general group that go to ATM machines, use TTL logic, and watch LCD displays. . .

As others have noted, it probably won't be quite the same, but may work. But from the numbers you gave, I guess the specified core must be a T-20-2, no? Whatever the core, you should be able to get an estimate of the Q that the toroid form will give you (for example, see http://www.amidoncorp.com/aai_ironpowdercores.htm), and you can make an estimate of the Q you'll get at the same freq with an air-wound coil, just to be sure you're in the ballpark. For coils about as long as their diameter, the Q is roughly 100*(diam,inches)*sqrt(f,MHz) There are air-core coil programs around that will estimate the Q more accurately, and the self-resonant frequency as well...Reg Edwards has one, for example. -- If I guessed right on the toroid core, you'd probably see a Q around 120-140 in the 5-10MHz region for your coil, and you'd have to use an air core coil roughly half an inch diameter to get that. (My coil program tells me that 11 turns of #22AWG 3/8" ID and a bit under 1/2" long will give you the inductance you want, at a Qu of about 150.)

Cheers,
Tom

All those xistors are "2S"-yaa-daa-yaa-daa-yaa-daa.
The Japanese for nomenclature each of those above
then:
2SC2827,
2SC3405,
2SD553,
2SD844
2Setc. :-)

Now you're better prepared to try cross-reference(s).

"HI" comes to mind...."it has a certain characterstic 'ring' to it."

It does not mean 'Hello'. It is the telegrapher's _laugh_.

Behold, James W signalled from keyed 4-1000A filament:

> Care to expand a bit on this?

Sure!

I found that the RDSon was too high with most MOSFET's. The best I could attain was a 1/2 volt drop at 1 amp load. When the CB linear came on, it increased the drop to 6 volts (60 amp draw).

So, I went to the auto wrecker and got a couple of 30 amp relays and a 100 amp contactor for the job and it worked perfect.

do a Google for something called the "Phillips Code" which will show you about a gazillion abreviations. It was used by WIRE telegraphers, as opposed to wire-less (radio) CW.

Also HAM = "Had-Alota-Money" (before i got into this hobby) :-)

Harv, AI9NL

interesting answer,,

the numbers listed are from a certain peice of equipment, you will need to consult the manufacturer for the values. what you listed wil not reference to anything. where are they from?

usually devices that start with D are diodes Q is for transistor R is for resistor C is for capacitor. the nubers are usually what number in wiring sequence or quantiy of the particular device

hope this helps

No, Hank, having a new number set to anything is the result of every manufacturer assigning THEIR own arbitrary number or letter ID to their products. The military and the government is stuck with a TOTAL variety of spare parts that can boggle the mind...and does sometimes tax the efforts of those responsible for maintaining the logistics of vital parts of EVERYTHING for our government's needs.

I've been up to my elbows in Mil Specs quite enough in the past half century and just accept it as part of the environment. If you consult those Mil Specs long enough, you will see that there IS an order on ID, nomenclature, and so forth. Not only that, but aside from COTS stocks, a tantalum cap built to a certain Mil Spec will be the same value, size, rating, and shape from another manufacturer. Same with resistors, inductors, etc., etc., etc.

Try that with more than one commercial component manufacturer especially when there's a production run going on and the parts supply is lagging and the parts from another manufacturer don't fit. Deep trouble time. Or one manufacturer may add on some suffix letters or numbers to a so-called "standard" part because they make an "improved line" of products and the purchasing department doesn't adjust to this other manufacture's IDs...

The center for Military Intelligence schooling and operations is at Fort Huachuca, AZ. They have a website with interesting stuff on M.I. history in it.

I would advise against soldering anything into it. What you describe
is a typical "patch antenna" that uses part of the existing PCB as a
sort of "ground plane." The impedance of the patch antenna will be
matched to the input impedance of the receiver's first stage and is
not guaranteed to be in the 40 to 90 Ohms impedance of, say, an
almost quarter-wave wire typical to an HT.

Just soldering in an extra wire length MAY work but there is no way
of telling - without a lot of other information about the receiver - what
the effects will be. It MAY be better but, in all likelyhood, will be
worse.

The RF environment of any inside of any building is unpredictable
for anything but gross results. All sorts of conductive things can
affect the RF field causing in-phase reinforcement of wavefronts or
out-of-phase attenuation of wavefronts.

There's a very easy test to do with no more than a coat hanger wire
stuck in a small block of wood. [done by a friend of mine needing to
do a presentation in a larger room than originally scheduled, some
years ago, but also for projection purposes] Cut the wire about
12 1/2 to 13 inches and stick it into the wood block (the block is an
insulator). Position it somewhere between the transmitter and
receiver by trial and error.

This is the most simple form of "passive repeater," in this case a
half-wavelength resonant thing at 433 MHz. All it does is to mess

about with the already-mixed-up wavefronts in the room (fairly well fixed by the building) such as to move a wavefront reinforcement towards the receiver. There's no amplification with that, of course, but it can cancel a deep attenuation at the receiver's location.

Does the room contain metal folding chairs? I've heard of those affecting wireless devices such as microphones. The dimensions of straight-line conductive objects in those chairs are close to a full wavelength at that frequency and many would be expected to change the overall wavefront pattern. If the effects are different when the chairs are folded and stacked, that is proof that they do.

Passive repeaters (of a more elaborate kind) have been used in "fringe areas" to improve reception, especially for a community that is behind some moderate hills. Those are just a high-gain antenna on one side of a hill connected by a feedline to another high-gain antenna on the other side of the hill. It works well enough without any electrical power supply of any kind.

A passive repeater Yagi antenna pair can be simple enough and small enough at 433 MHz even if each Yagi has three lengths (reflector, dipole, director) or just two (dipole and reflector). No power needed, just a short coaxial cable beteen each Yagi's dipoles. The Yagis should be at least a foot apart and preferrably at right angles (or slightly greater) to each other. That can be put at the side of the room or hall, one Yagi pointed towards the normal location of the transmitter, the other pointed towards the receiver location.

Such a Yagi can be built with #12 or #14 bare solid copper wire common to household electrical wiring. The dipole would be 12 1/2 to 13 inches long, the reflector about 3/4 to 1 inch longer than the dipole, the director element about 3/4 to 1 inch shorter than the dipole element. Each element can be spaced 4 to 5 inches apart. The elements could be mounted on-end, stuck in partway drill holes made in a piece of 2 x 4. Exact dimensions aren't critical... unless one wants to argue details to the end of time in newsgroups. :-)

>If possible I would like it to be somewhat omni directinal.

A passive repeater setup isn't precisely omnidirectional but it does allow a lot of freedom of movement in the general transmitter location.

>The product spec says it
>is (is that why the square ant and not a long skinny one???)

No. The internal patch antenna is fixed in shape by dozens of other factors. The fact that it is, in its largest dimension, smaller than a quarter wavelength makes its pattern approach, but not reach, that of an isotropic or point-source antenna.

>Also while looking online I see places that sell 433 mhz ant's for
>about 15$- They are made (I think) for handheld walki-talkies(??)
>would somthing like this help me.

No. A quarter wave whip for 433 MHz can be made from #14
bare solid copper for pennies and is self-supporting...and can
be soldered readily for adapting it to an adapter. I would advise
trying to fuss with either receiver or transmitter's antenna unless
you have a lot of experience under your belt and have access to
UHF-range test equipment.

A number of experienced people at the manufacturer have already
spent a lot of time on design to get the product in that shape and
small size. It may not be optimum (chances are it is a mass of
compromises) and may not be the best in ALL environments, but
fooling with it can result in it not working at all well afterwards.

Okay, but why pick an identifiction method that requires a manual?
Most other components this size, including theirs, just have the
relevant numbers printed on them.

Go to Google and search for "atomic clock". In the first 20 or 30
listings you should find hobbyist sites that have diagrams and maybe
even kits.

You might want to search at http://www.google.com using the terms wwvb decoder clock. There's plenty to select from and a number of kits available.

Hi,
Unless you want to have fun building a clock, there are many such clocks
or watches out there. I wear a watch. Very accurate in time keeping.

You can find a similar circuit, all hardware, at Hans Summers website
in the UK (I expect he will be along shortly to remind us where). :-)

That was Hans' senior project in college, made to receive Rugby
broadcasts on 60 KHz. The time code format of WWVB (also on
60 KHz) is slightly different. Most such projects today use a
Microchip PIC or Atmel microcontroller programmed to do nearly
everything in decoding and displaying, but to LCDs rather than
LEDs.

Since the microcontrollers in the 30+ "radio clocks" on the market
usually have some DSP routines to aid in selectivity and noise
reduction, the hardware content is VERY low and the prices are
cheap enough. We have two such at the house, an Oregon
Scientific brand bought 4 years ago (small in size, good for travel),
a Large display unit from La Crosse Technology bought at Office
Depot. We (wife and I) didn't pay $30 for either one and they
were not on a special sale. They run for over a year on a single
battery and automatically update to correct time if needed. The
NIST website (under Time and Frequency division) has a list of
available "radio clocks" on the market. NIST has all the info on
the WWVB time code, area coverage, transmitter details, lots.

If you wanted an LED display instead of LCD, I'd suggest getting a
commercial unit and adapting the LCD signals out to LED driver
circuits. That way the RF input circuitry, DSP enhancement, and,
especially the decoding, is already done. That decoding isn't all
that easy to do if you've never worked with this sort of thing before
and it is definitely NOT simple like a "one-tube superhet" project.

After 1844 (the year of the first commercial telegraph service in the USA, Baltimore, MD to Washington, DC), the blazing speed of the early electromechanical sounders made it necessary for commercial telegraphers to to use abbreviations for standard phrases in telegrams. It gave telegraphers a chance to send more telegrams during a workday, increase their profits, etc., etc.

A whole bunch of different two-number sub-codes were invented and used. Few survive to today since morse codes have survived only in amateur radio.

One of the enduring sub-codes is "73" meaning "Best regards." Hams use it on voice, as well. It has become traditional jargon.

Morse code did NOT begin as the character = <dot-dash group> but was originally ALL numbers! Morse got a financial and lab mentor in railroad heir Alfred Vail who is reported to have suggested a change from the all-number code to one where each letter, number, and common punctuation mark has a unique dot-dash group. This latter improvement, along with a way to increase the distance of a landline by using a "relay" of an electromagnet whose magnetically-coupled switch substituted for a telegrapher's key in an unmanned telegraph line relay station. Up to three such "relays" could be used on a wired telegraph circuit. That may or may not be the etymological origin of the word "relay" as the component we know today.

The final version of morse code coding still doesn't allow much real speed in communication so a number of abbreviations were used as well as telegraphers' own jargon. One of those latter was the "R" sent as or after simple queries, meaning "okay?" or "okay" respectively. The dit-dah-dit of "R" has a nice little pattern to it and is intuitive for that. It continued on into radio after 1896..."R" meaning "okay" or "all right." With WW2's widespread use of radio of all kinds, operators on voice followed suit with the phonetic alphabet "R" or "Roger." "Roger" as an affirmative caught on and became common

jargon on voice. In spoken language it has found its own niche in military use exemplified by "roger that!" meaning very affirmative. :-)

"Q codes" are an example of three-letter sub-codes to mean whole phrases, either as queries (followed by a question mark) or as responses (followed by answer information). Those came about in radio since the letter "Q" was seldom used in English words...and the transistor hadn't been invented yet. :-) "QSY" was a query as to the exact frequency of a station (with spark transmitters that was more of a guess) but stayed around until WW2 when it was used on voice and teleprinter as a command to change frequency. "QSY Frisco George to 6885" would be an abbreviated command on either a telephone or teleprinter military radio order wire in the 1950s. "QTH" is another that stuck around in other radio services referring to a location.

Of course there are the "10 codes" used by the various police in the USA during the late 1940s and 1950s. Dirty, Evil CBers picked up on those and used them as short-form jargon, much to the outrage of licensed amateurs, most of whom where not born in 1958 when CB on 11 meters was created. :-)

Component values are even given jargon. Back before International Scientific terms were standardized, small-value capacitors were rated in micro-micro-Farads, written "uuFd." Electronics industry folks spoke of those values in "mickey-mikes." It didn't help when the SI powers of a 1000 names were used...now those "uuFd" caps are rated in "picoFarads" written "pFd," are now referred to as "puffs." :-)

After the first transistorized portable radios appeared, common folk started calling them using only one word, "transistor." That term has been used long after vacuum tube portable radios disappeared and the "transistorized" radios were now using integrated circuits. Human beans will use any kind of name and jargon in some activity they consider very exclusive. :-)

So, Best Regards all around but no 88s (wife frowns on that...),

> "okay" or "all right."

"R" takes on extra significance in meteor-scatter and moonbounce communication. Meteor-pings can be so fleeting, and moonbounce is generally so weak, there have to be specialist QSO procedures.

These procedures strip the QSO down to its bare essentials. They involve lots of repetition, but they are very strict about requiring full confirmation both ways. Both stations must copy both callsigns, a signal report and the confirming "R" - if any of that is missing, it doesn't count as a QSO.

You and the other station might each have to sink a half-hour or more of concentrated effort into a single MS or moonbounce QSO... and in spite of the tenuous communication, there's a lot of satisfaction in knowing that the other guy is trying just as hard as you are. But in the end, the whole effort hangs on copying that final "R". There may be only one, and it may be only just above the noise level... but you *must* hear it.

So when it finally comes, that "di-dah-dit" pattern means a lot more than a casual "OK": it says "We-nailed-it!"

Kind of sounds like another CB urban legend to me. Usually only the
receiver is mixed with 455 kHz, not the transmitter. And I've found that
most CB LO's are at 10.240 mHz. You could easily construct a transmitter
for that frequency but not legally operate it.

One serious shortcome of this system is that a tech in the field would have
a tough or impossible time replacing a known defective capacitor, say
shorted, with the correct value without a cross reference of mil numbers vs
value. The system is oxymoronic in this case as is military intelligence in
many more and I served!

OK, let me give you a few example lines from the manual:

uF Case tol. Failure Rate (%/1000hrs) DC Leakage in uA
Code % 1.0 0.1 0.01 0.001 25C 85C 125C

5.6 A 5 5001 5201 5401 5601 0.3 6 7.5
5.6 A 10 2241 2481 2721 2961 0.3 6 7.5
6.8 A 5 5002 5202 5402 5602 0.3 6 7.5
6.8 A 10 2242 2482 2722 2962 0.3 6 7.5
6.8 A 20 2243 2483 2723 2963 0.3 6 7.5

So a M38003/01-5001 is unique. I left out the dissipation factor for simplicty.

As you can see, there is much more information in this code number than just the capacitance value and the voltage. When a component is bought to this specification, it will meet it. If you buy a random FF uF VV volt capacitor, you have no clue as to what you have with respect to leakage, reliability, dissipation factor and the like.

And if you want to see an example of a real military codebook, I have
one up on my website at <http://mikea.ath.cx>, third link down:

US Army Training Codebook, WW2
Divisional Field Code, Training Edition No. 2

Somehow, "73" seems a lot simpler than "OKXV" or "3797", as found in
<http://mikea.ath.cx/codebook/pp064-065.jpg>.

And yes, I _MUST_ OCR the pages or type them in or something; the
images are too bulky and slow, even though they are an exact
representation of the pages.

Yes, I have one of these clocks also. The thing is, these clocks
are set 6 times in a 24hr perod by the WWVB signal. The rest of the
time the time base is an ordinary crystal. I want my clock to be
set on a more continous basis. This could only happen with the
continous decoding of the signal. This is how the "professional"
clocks, such as those made by Spectracom work.

You might consider the old Heathkit clock, which still turns up cheaply
at hamfests now and then.

If you build your own, make sure you use nixie tubes. That's important.

Roger that, Ian. :-)

I meant no disrespect for moonbouncers or scattered scatterers, was
just ruminating on the mass of jargon and phrases that have become
commonplace in radio communications in many radio services, both
civilian and government. "Roger" as an affirmation word has been
with us for six decades and seems entrenched as an equal to "okay"
over radio.

Using "roger" instead of the word "okay" (common in several
languages, not quite as common as "hamburger") seems a sort of
tribal speak kind of exclusive jargon. The same with vocalized "73"
instead of saying just "best regards." Same number of syllables
and takes about the same time to pronounce. :-)

Thanx all for the info on the antenna. I looked in the recever and
found the antena is *gasp* about 6.5 inches long!!! It is bent inside
the case into a square. So if I was to straighten and piont it straght
up would this help with range? Is the reason it is bent inside just to
hide and make the recever smaller or is it somehowe helping the
recever be omnidirectional? Agian - thanx for all the input!!!

"Best regards"

It derives from landwire telegraph usage, and appears as early as 1857 in a list of abbreviations. Some of these telegraph abbreviations were transitioned into radio use and have survived because of their obvious utility.

In 1859, Western Union standardized on the "92 code" in which the numbers from 1 to 92 were assigned meanings. It was in this list that 73 got its present meaning. Later more numbers were added. Here's a partial list:

1 Wait a moment
2 Important Business
3 What time is it?
4 Where shall I go ahead?
5 Have you business for me?
6 I am ready
7 Are you ready?
8 Close your key; circuit is busy
9 Close your key for priority business (Wire chief, dispatcher, etc)
10 Keep this circuit closed
12 Do you understand?
13 I understand
14 What is the weather?
15 For you and other to copy
17 Lightning here
18 What is the trouble?
19 Form 19 train order
21 Stop for a meal
22 Wire test
23 All copy
24 Repeat this back
25 Busy on another wire
26 Put on ground wire
27 Priority, very important
28 Do you get my writing?
29 Private, deliver in sealed envelope
30 No more (end)
31 Form 31 train order
32 I understand that I am to ...

33 Car report (Also, answer is paid for)
34 Message for all officers
35 You may use my signal to answer this
37 Diversion (Also, inform all interested)
39 Important, with priority on thru wire (Also, sleep-car report)
44 Answer promptly by wire
73 Best regards
88 Love and kisses
91 Superintendant's signal
92 Deliver promptly
93 Vice President and General Manager's signals
95 President's signal
134 Who is at the key?

"19" and "31" refer to train orders of two different types (absolute and permissive). They were so well known that the terms "19 order" and "31 order" were still in railroad use in the 1970s, after the telegraph was gone from railroad operations.

The Morse code used in US wire telegraphy was the "American" Morse code, which shares some codes with the "Continental" code we still use today. (The continent referred to in the name is Europe, and it became the standard code for radio work early in the 20th century).

The abbreviation "es" for "and" derives from the American Morse character "&" which was dit dididit. The prosign "SK" with the letters run together derives from the American Morse "30", which was dididididahdit daaaaaaaah (extra long dah is zero in that code).

There are some urban legends about Winchester rifles and such, but they do not stand up to historical fact.

Hmmm...More power..I like it! I am going to play with the ant on the
recever some more but I may just crack open the transmitter if all
else fails...
Thanx
KEith

Thanx for the info! I really like the idea of a passive repeater. I
will give this a try!
There are in fact about 500 metal chairs in between the front and
back...so that mey be hindering the range.I did a test at home and can
only get about 10 feet range..I find that alot of my rf stuff is very
limited at home I think it is because I have a bunch of wireless x-10
stuff...
Anyway thanx for the great advice!
Keith

For some time now the web site has indicated that would happen. I think
many of Sheldon's kits are available from Kanga U.S., but I have never seen
anything on Bill's website as extensive as Sheldon's.

You'll find that most of the schematics on the net for atomic clocks are
of the crystal variety-they set once or twice a day with WWVB and the
rest of the time use a crystal. You'll have to do some digging to come
up with something that does continuous decoding, but I'm sure it's out
there.

1922. Re: MFJ balanced line tuner efficiency?

Newsgroup: rec.radio.amateur.homebrew

If a tuner doesn't burst into flames with a 1 KW transmitter then it must be resonably efficient. There must be a lot less than 1/2 S-unit loss in signal strength.

Why all the concern about efficiency of tuners? Old wives' ?

Reg.

I have a similar page here from the Sprague/Vishay catalog. In this
case it just happens to be for some caps which I picked up surplus
which are marked M39006/25-xxxx.

In this case the xxxx code pins down the tolerance and failure rate,
just as the Kemet does above (note that everything else above is the
same.) OTOH, the Sprague/Vishay caps are also labeled with their C and
V ratings, as well as the tolerance. Only the failure rate is left
unexplained. There is also an H-code for high vibration which you
might need the catalog page to interpret.

BTW, both manufacturers have a code for an M failure rate, which is
1.0% per 1000 hours. I find it hard to believe that anyone would buy
such a device, especially the military. The ones I got were the R
rate, .01% per 1000 hours. Those are the best that they offer and I'll
bet those are the only ones that ever get sold.

So I still don't think it's too much to ask that the most important
data be printed out separately.

Obviously, I don't tend to think like the military....

While you've got a legitimate point, you've got to realize the function of the part number. If you're a technician servicing a piece of military gear, you replace a 20035942 *ONLY* with a 20035942, not *ANY* other capacitor, regardless of its value. To order a replacement, you put in a requisition for a 20035942. Now, it's vital to you that the capacitors in the stock bin or coming in from the supply system have 20035942 printed on them, but it's not important that the value is. The technician can find the value in the parts list in the manual and likely on the schematic. The stark fact is that the military supply system wasn't created and isn't maintained for the convenience of the ham who's working on surplus gear.

You'll actually find this is true throughout the industry, with many ICs, for example, having only the customer's part numbers on them. Go to a flea market anywhere around here where I live, and you'll find lots of components with only Tektronix part numbers on them. You'll also find lots of folks locally who can tell you what they are, at least generically. I'm sure the same thing is true for HP and Palo Alto, Motorola and Phoenix, and so forth.

It's not that you don't think like the military -- it's just that when they developed their stock system they didn't take into consideration the inconvenience it would cause you, me, and other hobbyists.

The equipment is "out there" but the closest you will come to any
sort of detailed description/circuitry is the NIST site itself. An
example is the IRIG range timing, usually derived from a rubidium
or cesium standard, they may do an update via the NIST time code
but more likely it will phase-lock to the WWVB carrier.

"Ordinary" quartz crystals in the radio clocks can have all sorts of tolerances on their frequency. There are 86,400 seconds in one day. A common 50 ppm (parts per million) tolerance (5 x 10^-5) would show a 4.32 second per day maximum error. By stabilizing, or perhaps trimming, the oscillator circuit in a radio clock, one can get it down to 5 ppm or 0.432 seconds per day error.

However, an update circuit might exhibit a quantization error of 1 second which would be additive to the radio clock's crystal oscillator tolerance and possibly defeat the "accurate setting."

As a practical matter, I used to spot-check the Oregon Scientific radio clock against the WWV ticks and found it to be better than 6 ppm, the worst error being about a half-second. I just checked again and found it to be bang-on the WWV ticks. :-) The big radio clock is in the same sync on seconds with the little one.

To avoid quantization errors of setting the internal calendar clock, the "update" could advance or retard the crystal through a VCXO circuit driven by a D-to-A whose digital correction is derived from a comparison of the NIST time code to the internal calendar clock. Kind of a very slow phase-lock done the hard way. Might take days to get in phase. :-)

I'm very satisfied with better than +/- 1 second error from these two inexpensive things and won't change them. Ain't in the TV BC biz like CBS affiliate stations back in '56 that needed +/- 1 second maximum errors to "take network" when scheduled or lose money.

Anybody give this amp design a try? I just got the schematic corrections from KN6EK (one of the authors) and I'm anxious to build it. Looks pretty straightforward and simple. Any words of wisdom from those who have gone before?

What I did is use a GPS-disciplined receiver to give me a highly
accurate 10 MHz standard. The receiver costs $250 from
www.buylegacy.com but you'll end up paying (way too much) for a power
supply/line lump and the antenna. I also spent money on software to
use with it on my win2k box.

Every 10 minutes that software updates a web page with the sky view
and how the high-grade crystal oven is functioning, including
estimated error over 24 hours if it loses contact with the GPS
satellites.

No, because coils actually do melt and switch contacts do arc, even at the 100W power level. This is because commercial tuners are notoriously over-specified, and always use components that are at least one size too small.

Rule of thumb: divide the rated power level by at least 3 - and you still may not be entirely safe.

The T-match tuner can match a very wide range of impedances, but it is also prone to operator error - specifically, using too much inductance.

For the lowest possible stress on the components, you must use the *lowest* value of inductance that will allow the two capacitors to be adjusted to give an impedance match.

You can also get a match using higher inductance, but the internal voltages and circulating currents will be unnecessarily high. That's where the inefficiency problems arise. With T-tuners, these problems are especially acute when trying to match low impedances at low frequencies.

The ARRL Antenna Handbook has a lot more to say about this, and the CD-ROM includes a program that lets you map out the efficiency as a function of load impedance and frequency. Some of the numbers down in that low-frequency, low-impedance corner are plain scary - most of the power is going into the tuner itself, and it comes out as smoke.

This situation is not entirely the fault of manufacturers. It's we customers who demand a tuner that claims to match every impedance, at every frequency, with the highest possible power rating, and all for less than the lowest possible cost. The T-tuner probably comes closest to this ideal, which is why they choose that configuration... but it isn't always the right choice.

Reg, you must be joking .... 1/2 S unit isn't much when an S-unit
on most of those plastic boxes is around a few decibels, suppose we
are not talking about real S-units any more, then you would get too
many complaints of reporting 55 when everybody else give 59+. Those
modern American tuners (unlike those good old KW tuners) are not
really balanced, they use a balun on the output, and forget about
earth current

I was a GCA radar tech in the RCAF in the 1960s and in one of the excercises (war games) we had to find and fix a fault so the incoming aircraft wouldn't crash, it was zero visibility . Sometimes it was as easy as a bad or loose tube, but some seargents had subchassis with cold solder joints, shorted black beauty capacitors or fried resistors. Time was critcal as the weather was closing fast and the aircraft was low on fuel. Sometimes the excercise left us without many parts, partially functional test equpt, and only partial manuals. To better simulate battle conditions, one end of the hut could be on fire and CO2 smoke to hinder visibilty! A shorted .01 uF 400VDC black beauty was easliy replaced with a .01 uF 600VDC or .02 a fried 22K 1/2 watt with a 22K 2 watt or something close. Color codes were quite useful in many cases. The objective was to save the aircraft using limited resources. Today I don't think we see component level repair in the field but in battle anything may be necessary for survival. I'd much rather have something with component values rather than a bunch of codes that required decifering. I still contend this is a result of "military intelligence." And the codes make it tough on us hobbyists but we not under a critical time crunch and with the Internet it's usually a piece of cake.

In the sixties that was possible. But now you can't really fly by the
seat of your pants. Repair is by replacing LRUs (Least Replaceable
Units). Even if the LRU makes it back to the depot for failure
confirmation, it may not be repairable. 6, 8 or 12 layer PCBs cannot be
readily repaired. And would you trust one that was repaired if it did
not go through a burn-in cycle afterward? Would you depend on a
fail-safe circuit to prevent a nuclear launch if it had a component
replaced in it that was "close enough?" Maybe in your cars brake system,
but not on my missile!

> but not on my missile!

True, in the 'close enough' stakes, but it is well worth reflecting that 90% of simple systems use a relatively small 'subset' of parts from the avilable world pool. An engineer, with one each of the IC's for a range of boards, and a few dozen resistors and capacitors, can potentially repair most faults on such boards 'on site', especially if the board is designed with this in mind (possibly with some form of self diagnostics for many parts). However if the same units are built with SM parts in quantity, using custom IC's, the solution becomes to carry a complete replacement board. Doing this for a few dozen products is often not practical. The problem here is that the custom IC/SM solution is cheaper once production reaches a reasonable level, but is not the best solution where the units are going to be a long way from 'spares'.

I designed a range of units used on sites across many third-world countries, and it became necessary to deliberately design the units with both redundancy, and repairability in mind. Given that the service engineer may have to travel 1000miles to get to a unit, having it so that repair is likely to be possible, was a vital design criterion. The parts list was deliberately 'shrunk', retaining as far as was practical a limited range of parts used in all. Unfortunately the relative costs of truly 'mass' production, combined with robot construction/assembly, make such designs a 'dying art'...

Best Wishes

> old hanbooks but wanted to hear from the group.

The tuning range of the VFO in the HW-101 is 5 to 5.5 MHz. Its output
is low impedance and only about a volt or so.

The T-60 requires VFO output in the 80 and/or 40 meter bands. It needs
more output (several volts at least) than the HW-101 vfo can provide.

The mixer solution suggested by others will work, but it's not simple
and requires a bit of doing to get going.

Knight did not make a matching VFO for the T-60. There *was* a Knight
VFO, but they are relatively rare.

One very good yet simple VFO design is the QST article (February 1962,
IIRC) called "An Easy To Build VFO" by W1ICP. Will drive almost any of
the classic "Novice MOPA" transmitters like the T-60.

Ian,

Quite rightly, you blame the melt down of the tuner not to the tuner's intrinsic inefficiency (which none of them have) but to the abuse inflicted on it by the user with the help of a transmitter.

All tuners are high-efficiency devices when operated within their ratings. They can't help being otherwise. They have only a length of wire in the form of a coil and a condenser.

Reg.

If your design criterion is that the equipment be field repairable with readily available parts, then so be it. I have no argument with that! But in the high-reliability military electronics world in which I worked in the late 60's, that was not possible. Would you believe that one printed circuit card, 4 in by 6 in, was needed just to implement 4 flip-flops using descrete components. Each component, yes even a carbon composition resistor, had a serial number on it. Why? So it could be traced back to the lot from it which it had been selected if it failed. And boy, did those components have to be reliable! So that's why the military specifications with their "strange" component markings were invented. Expensive? Lordy, lordy! I was very shocked one day when I requisitioned a capacitor from stock to compare to a rejected one. The price for that unit, a precision paper mylar cap. was $100 - in 1970's dollars! I almost fell out of my chair! And now you can buy stuff like that, surplus, for just pennies on the dollar...and with their strange markings.

I have a bag full of CSR13G825KR's! Anybody need one?

In the late 1960s I was working in both commercial, space, and military electronics. Only the space electronics (unmanned space-craft done at Electro-Optical Systems, EOS, in Pasadena, CA, a Xerox division) was there traceability to that extent, plus the "JAN TX" or tested-extra solid-state components. That was with reasonable logic since no company would pay per diem for in-the-field space-craft repairpersons... :-)

I might note that the little labels used to mark the components were of a selected brand...to avoid outgassing in vacuum of space and thus coating some other spacecraft instrument or sensor. Some have called such a practice "braindead procedures by NASA" but those people are themselves braindead for not thinking through for operating in a very different environment.

Since that time I've been involved in a lot of other DoD electronics and have never seen that level of traceability except in certain prototypes and then used solely for development testing. NASA man-rating specs - not Mil Specs unless called out for common types - required screening and traceability for a very good reason that humans were aboard those spacecraft (STS or "shuttle"). Astronauts shouldn't be required to get down to the PCB level and unsolder bad components and resolder new ones in microgravity for one reason. Another reason is that they can't GET to a part such as the ignitor of an SSME (Space Shuttle Main Engine, built at Rocketdyne Division of Rockwell International in Canoga Park, CA, - now a division of Boeing Aircraft). That ignitor was often called a "spark plug" in-house but was really a redundant astable multivibrator turned on remotely and a driver for an external arc gap...the entire "ignition system" in one extremely clean (had to work in pure oxygen environment) little unit that had to work just fine in vibration you couldn't possibly imagine.

Much military radio and electronics equipment bears something resembling screening markings on modules but any research into that will show they are merely in-house or depot markings for ID and other things, not traceability. If you see the insides of an AN/PRC-104 HF transceiver or an AN/PRC-119 VHF FHSS

transceiver, you will see what I'm talking about.

>Would you believe that one
>printed circuit card, 4 in by 6 in, was needed just to implement 4

That's not at all strange for the late 1960s. Integrated circuits
weren't there to use, and had only begun to be Mil Specced.
Those were new from Texas Instruments and still the old DTL or
Diode-Transistor-Logic.

The IBM 360 and RCA Spectra 70 used discrete-transistor PCBs
in the 1970s. IBM didn't go into TTL ICs in a large way until the
IBM 370 VM and production starting around 1975.

>Each component, yes even a carbon

>that, surplus, for just pennies on the dollar...and with their strange
>markings.

I'm going to challenge the veracity of that claim due to "having been
there, done that," and only seeing that in NASA electronics.

Also, I have yet to see any "surplus" spacecraft, including the
engineering and test models that never flew.

Back in 1974 I and a co-worker were stuck in Galveston, TX, for an
RCA Corporation field test. We visited the Manned Space Flight
Center in nearby Clear Lake and did a walking tour on a Sunday,
unescorted as was the norm on Sundays there. I wanted to show
the friend the Solar Wind Spectrometer instrument built for the
ALSEP (Apollo Lunar Surface Experiment Package) in 1967. I had
handled all of the SWSs when they were built. All of the ALSEP
modules - except the SWS - were arranged around the "left-over"
Landing and Ascent stages in the lobby. I snagged a docent and
asked about the "missing" instrument. She went off and returned,
said "sorry, it is still being used in a lab experiment." Seven years
later and it was still working...after having gone through some tough
environmental testing on earth.

NASA manned or unmanned electronics is subject to the maximum
in traceability. Military fielded electronics has had traceability
limited to specific lots identified through records and specified
percentage sampling tests on those lots. Samples may be tested
to destruction depending on the Mil Specification. All that TESTING
effort is what drives the parts cost up AND having to package spares

in extra-special protection envelopes and containers since they may be sitting waiting in some terrible environment somewhere in the world. World War 2 production and logistics taught the U.S. military much about needing spares and how to ship and store everything. USA has always been darn good about logistics and supply and has been successful at it.

To those folks who want to sneer at "military intelligence," fine. Nobody is forcing them to like military electronics or the military. Let them build things for room-temperature environments using surplus CB radio parts or those from TV sets. However, when those also sneer at little things like nomenclature about high quality stuff available surplus at cut rate, it does warrant a strong response.

Roy Lewallen had the succinct response. :-)

If I'm that tech, how do I correlate that p/n with this cap on the
schematic? Does the schematic have both the value AND the p/n on it?

I understand your point about using the exact replacement, but I don't
see why a part should not have BOTH sets of data. To me, that seems
like it adds a lot of value to the part.

Typically, the schematic will identify the part by "circuit number", say C143 (and might or might not show the value), and it'll be on page A4B3, which is the schematic for board B3 in larger assembly A4. In the same manual, there'll be a parts list for A4B3, where you can find the description of C143, along with its part number. It would certainly include the value, type, and probably the tolerance, which are important to know when troubleshooting. Sometimes it'll tell a little more, if there's something particularly unusual about the part. But the full description of that part #20035942 only appears on a document that's typically many pages long and fully describes its specifications. There might be 100 different part numbers for 4.7 uF, 10%, 50 volt tantalum capacitors, each with different specifications for reliability testing, temperature range, ESR, mechanical lead strength, vibration tolerance, tada, tada, tada. They are *NOT* interchangeable in the military or commercial environment. Substitution could result in failure at a critical time or place with incredibly expensive, disastrous, or fatal consequences.

When replacing the part, the only thing that's important to the technician is whether the replacement has the right part number. If it doesn't, the part doesn't go in, regardless of what its capacitance value might be.

Yep, stamping the value on the capacitor would undoubtedly add value to the part for you and me. But again, the military just wasn't thinking of us when it set up its stock system.

I recently put together the old AC-1 tube transmitter for the 40 m band.
And it works, kind of.

It oscillates nicely but does not have any power.
I know, it is not supposed to have much power but this one is weaker than
weak, the output couldn't drive any antenna.

I was wondering if there are AC-1 owners/builders around here who could
suggest a few things to try, who are knowlegable about this thing.

Did you do any voltage or current measurements? While I haven't played with a real AC-1, I've built many similar 6V6 single tube transmitters. I have the circuit for the AC-1, and it looks pretty similar to some I've built. First thing to do is measure the B+ to the plate and screen. Next, open the plate feed where it connects to the filter capacitor and insert a milliameter. With the "load" capacitor at maximum, adjust the "tune" capacitor for minimum current. Take a set of readings and get back to me.

Hi,

I need to add some 2 port components (Mini Circuits GALI MMICs) to the Designer SV user or personal library. Cloning one of the MMICs in the syslib was easy but I have problems with all the rest. For instance: Do I have to type in the name of the external .s2p file in the in the data source field ? What do I have to type in the properities window? What is the syntax of the CircuitNetList line? The help file is not too comprehensive.

Any ideas?

Thanks

Peter

In fact, it's becoming much less common to find parts in commercial equipment with only the OEM user's part number rather than the manufacturer's PN on them. Partly this is being driven by contract manufacturing of the boards, but it was a trend even before CM became so common, in my experience.

Roy's comments about military techs are slightly idealistic, if I relate things to my personal experience some years ago. My shop supervisor at a remote site quickly learned to trust my judgement in finding ways to get things repaired and functioning reliably when parts simply weren't available. When it comes to a decision between completing a critical mission using a part that gets you through the mission, and waiting six months for a part, guess which wins. You can find info about some of that sort of thing on the NASA web site. Astronauts don't wait for delivery of XPQ1453762 if their lives (or even an expensive experiment) can be saved by using something on hand. Clearly, you'd prefer to use the exact part specified, or a documented replacement, but there are lots of times when waiting for that would be very poor judgement. (Darwin award candidates??)

OTOH, do NOT expect modern parts to be fully labeled. Don't expect 0.1% SMT resistors to have anything on them telling you that they are 0.1%. Don't expect 0603 and smaller resistors and capacitors to have ANY marking, though some do. Don't expect SOT-23 and SC-70 parts to have anything but a simple 2 or 3 character code on them. Some (most?) SMT tantalum cap manufacturers don't seem to put a marking on them that tells you which series they are (std ESR, low ESR, extra-low ESR, fused, mil-spec...).

And count your blessings that you're dealing with electronic parts, where labelling with the value is pretty common. That's not the case with most mechanical parts, for example. Would you expect Honda pistons to fit any Toyota engines? Have you ever seen ANY springs labelled with their spring constant, let alone any of their other parameters? Most aren't even labelled with a part number.

Finally, there IS a reason that schematics don't always have values or manufacturer's part numbers on them, or even house part numbers, but only a reference designator. That's because values (and therefore the part numbers) may well change over time. It's a lot easier and less error-prone to maintain only one changing document: the material list used to build the board. Not everyone agrees with that, and in fact I do prefer to have values and mfgr's part numbers on my schematics.

Cheers,
Tom

>
First thing is the voltages and currents, as already suggested. Then there's
the size of the coil and your tuneup technique.

What sort of load do you have connected to the output?

Help
I've got some HP 33123A, SPST PIN switches rated 100MHz -15GHz, they aren't in my HP catalogue and I can't find any info about them. I specifically need to know how to drive them and hope that I can switch them at a 1KHz rate to give me modulated test signals, they are a small rectangular box with 3 SMAs.
Thanks in advance for any information.
Thanks
John

Doug, thank you soo much for your email, you just fixed my transmitter.
Well, sort of.

As I tried to do what you had suggested I noticed that someone (I could
never have done such a thing) had connected the 18k resistor (which is
connected to grid # 2 on one end) on the wrong end of the choke.
I guess that choked it.

Now we don't just have oscillations, there is even a little bite to it.

I am relatively new to all this and I am just putting together the necessary
equipment. So a 50 resistor serves as my dummy load and a meter connected to
the dummy load indicates around 10 volts RMS. If I did my homework that
would indicate around 2 watt output. All this at B+ of 200v and an anode
current of about 35mA (I am running the transmitter off an adjustable bench
tube power supply at this point).

Does all this compare with the numbers you get with your transmitter??
I will need to build a power supply for the final version and would be
interested to know what you use for B+. In order to get 5 Watts I would have
to crank up the B+ quite a bit.

Actually I don't care at this point since I am still practicing for my code
exam, so I can't even use the transmitter right now.

How do you monitor your transmitting tone with a device like this.

Doug, thanks again, I am quite happy now

Uwe

I was thinking of the value it would have to the tech, in helping him
to make sure that the part he was looking at on the schematic and the
part that he was replacing in the circuit were the same item.

If he has to trace the item from the schematic (C437) to the parts
list (M390009/xxxx) to the chassis (M390009/xxxx) that's an extra step
where time is wasted and a mistake could be made. Both would be
counterproductive, in any environment.

Mine is set only once per day, sometime between midnight and 4 am.

I was under the impression that the reason this was done is that the
signal is too weak to be decoded during other times of the day. In fact, I
have some (admittedly very inexpensive) atomic clocks that have *never*
decoded the signal here in Florida.

Hi,
What is the best homebrew antenna our there to make? I have a 50ft tower that I have had a 22ft something omni telescoping aluminum antenna with some as long as possible ground planes (4). It works good on most bands, I have a good antenna tuner. I have to bring it down and fix it so wondering what alternatives are available to throw back up. I like to keep the omni style. What would be a practical length for the whip and or is there a copper wire style antenna that would perform better? Thanks for opinions!!!

Actually, the letters in prosigns are run together:

...-.-

didididahdidah

That's why you see the SK or VA written with a bar overline in books on the subject.

It's actually a contracted version of the American Morse "30" meaning "end of work, no more to follow".

>73 is used because of the way it sounds....
>
>dah dah di di dit di di dit dah dah
>

Except it doesn't sound that way in American Morse, where its use originated. That rhythm is one reason it stayed popular among radio operators but the true origin is the old land wire number code lists.

I run my 6V6's at about 325 volts on the plate, 250 on the screen. The plate is loaded to about 40ma, which is about 13 watts input. You can push it beyond this, but there's really no point since you have to quadruple your power to gain one S unit on the receiving end. You'll get about 8 watts out which is fine. If you want something heftier, you can go to a 6L6, 807 or 6146 tube. There is a compromise with single tube transmitters though, as the power goes up they tend to chirp, that is, the frequency slides a bit as they are keyed. It's not objectionable on the 6V6 transmitters, which is why I favor this power level.

I started out in 1954 with a surplus ARC-5 receiver and a simple 6V6 transmitter. With it I gained code proficiency and managed to work 28 states before my Novice licence expired. (They were only good for a year back then.)

For monitoring, you can just use your receiver with the antenna disconnected, or you can construct any number of monitor devices which you will find in the ARRL handbook. You can get more sophisticated but you don't have to. There is a special satisfaction in communicating with very simple equipment.

Hi all,

Is there some black magic required to get higher order harmonics out
of an oscillator?
I'm only trying to get 17.2Mhz out of a 3.44Mhz source and am thus far
failing spectacularly. I've tried everything I can think of so far to
no avail. All I can get apart from the fundamental is a strong third
harmonic on 10.32Mhz, regardless of what I tune for. I've tried
passing the osc output through two successive inverter gates to
sharpen it up, but still nothing beyond the third appears after tuned
amplification for the fifth. I no longer have a spectrum analyser so
can't check for the presence of a decent comb of harmonics at the
input to the multiplier stage but can only assume the fifth is well
down in the mush for some reason. I could change the inverters for
schmitt triggers and gain a couple of nS but can't see that making
enough difference. What about sticking a varactor in there somewhere?
Would its non-linearity assist or are they only any good for even
order harmonics?
Any suggestions, please. I'm stumped! :(

HOW TO MAKE EASY MONEY!!!!!!!!
: This seems to really have potential. This is the way the original post appeared when I first found it. Read it all then decide for yourself. It works for me! I found this on a bulletin board and decided to try it. A little while back, I was browsing through newsgroups, just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $6.00! So I thought, "Yeah right, this must be a scam", but like most of us, I was curious, so I kept reading. Even though the investment was a measly $6, I had three questions that needed to be answered before I could get involved in this sort of thing. 1. IS THIS REALLY LEGAL? I called a lawyer first. The lawyer was a little sceptical that I would actually make any CASH but he said it WAS LEGAL if I wanted to try it. I told him it sounded a lot like a chain letter but the details of the system (SEE BELOW) actually made it a legitimate legal business. 2. IS OK WITH THE POST OFFICE OR IS IT MAIL FRAUD? I called them: 1-800-725-2161 and they confirmed THIS IS ABSOLUTELY LEGAL! (See 18, h sections1302 NS 1341 of Postal Lottery Laws). This clarifies the program of collecting names and addresses for a mailing list. 3. IS IT RIGHT? Well, everyone who sends me a buck has a good chance of getting A LOT of CASH ... a much better chance than buying a lottery ticket!!! 4. WHAT IS THE BUSINESS? You are in the business of collecting mailing lists and recruiting new list developers. These questions answered, I decided to proceed. The instructions said that you have to send $1.00 to each of the 6 names and address stated in the article. You then place your own name and address in the bottom of the list at #6, and post the article in at least 300 newsgroups. (There are thousands) No catch, that was it. So, I invested the measly $6.00. Well GUESS WHAT!! Within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made about $25.00. By the end of the second week I had made a total of over $1,000! In the third week I had over $10,000.00 and it's still growing. This is now my fourth week and I have made a total of just over $42,000.00 and it's still coming in rapidly. It's certainly worth $6.00, and 6 stamps, I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works. Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it. It seems likely to me that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy! Suggestion: Read this entire message carefully! (print it out or download it.) Follow the simple directions and watch the money come in! It's easy. It's legal. And, your investment is only $6.00 (Plus postage) IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; and it is virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends. PLEASE NOTE: Please follow these directions

EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions. You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list. Here are the 4 easy steps to success: STEP 1: Get 6 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST include your mailing address, the date and your signature." Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery). Next, place one paper in each of the 6 envelopes and seal them. You should now have 6 sealed envelopes, each with a piece of paper stating the above phrase, your name and address, and a $1.00 bill. What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6 envelopes to the following addresses:
: 1 .)CRISTIAN MURO 1200 brookside dr, san pablo,CA 94806,USA
: 2 .)JOHNATHAN WOOLFSTON 1010 AVE, BROOKLYN, NY 11230, USA
: 3 .)ADRIAN GUTZMORE, FLAT9, 4BEECH TREE BANK, PRESTWICH, MANCHESTER, M25 1BH, UNITED KINGDOM
: 4 .) SADIA GHAZAL,H-NO.1237,ST NO-10, SECTOR I-10/2, ISLAMABAD, PAKISTAN
: 5 .)MICHAEL CRIST, 8294 WHITERIDGE CIRCLE NW, NORTH CANTON, OH 44720, USA
: 6 .) Susan Doyle 16 Clinch St., St. George NB, E5C 3C8 Canada
: STEP 2: Now take the #1 name off the list that you see above, move the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number 6 on the list.
: STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 300 newsgroups. (I think there are close to 32,000 groups) All you need is 300, but remember, the more you post, the more money you make! This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal lottery laws. PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions. Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way.
: NOTE: You want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.) So, as each post is downloaded and the directions carefully followed, six members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the #1 position you will be receiving thousands of dollars in

CASH!!! What an opportunity for only $6.00 ($1.00 for each of the first six people listed above) Send it now, add your own name to the list and you're in business!
: DIRECTIONS FOR HOW TO POST TO NEWSGROUPS---------- STEP 1) You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select 'copy' from the edit menu. This will copy the entire letter into the computer's memory
: STEP 2) Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the lis
: STEP 3) Save your new notepad file as a text file. If you want to do your postings in different settings, you'll always have this file to go back to.
: STEP 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions.) STEP 5) Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your first one! Congratulations...THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 300** That's it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O. Box due to the large amount.of money you'll be getting. VIEW THIS SITE ITS AMAZING!!! http://extremepowerline.com/28088

Dennis,

I don't know what you mean by ordinary crystal, but even.001% is not very good. You may want to look at high accuracy temperature compensated oscillators. Depending on where you live, you may actually be able to phase lock your oscillator to the WWB carrier. You would have to use a phase detector that does not pull you off to one side if you lose the signal. Also, the ~3.58MHz color subcarrier on some TV stations is locked to a cesium standard.

There must be something killing the fifth harmonic, which should be present at (1/5) of the amplitude of the fundamental in a square wave. That's a pretty strong component.

If you can amplify the output of the source and then square it up sharply, the fifth harmonic ought to be pretty easy to extract. The larger the amplitude of that square wave, the larger the amplitude of the fifth harmonic, of course, so amplification is your friend here -- but you may want to shield very well indeed to keep other components out of places where they don't belong and may cause trouble.

Have a look at
<http://hyperphysics.phy-astr.gsu.edu/hbase/audio/geowv.html>
for a lot of stuff that you probably already know.

Best of luck, and please keep us posted.

According to Fourier, at some mark-space ratios of a square wave certain harmonics may be missing from the spectrum.

Just generate a a train of very short sharp pulses from the oscillator and you will find all the harmonics are present allbeit with reducing amplitudes. A single transistor should do the job.

No black magic, you just need to filter for the fifth harmonic. I'm extracting the 16th harmonic of 64 MHz out of a MMIC, and retuning the filter, can actually extract a little more 15th than 16th. You can generate a comb generator to do the job of generating large quantities of all harmonics, but for this simple of a job, it'd be overkill big time. Either make a better filter, amplify your fundamental more before filtering, (the 5 volt digital squarer ought to put out +17 dBm) or check the HP app note AN983 and take advantage of "filter gain".

In RF circles, the 'normal' way to do this would be a simple Class C amplifier with a collector load tuned to the fifth harmonic. In calls C, conduction only occurs for a small fraction of a cycle which produces a correspondingly higher proportion of higher harmonics than a square wave.

et.com>) about 'Extracting the 5th Harmonic', on Fri, 12 Mar 2004:
>According to Fourier, at some mark-space ratios of a square wave certain
>harmonics may be missing from the spectrum.

For a waveform like this (use Courier font):

```
_____
/ \ /
_____/ \____________/
```

with rise-time f, dwell time d, fall time r and period T, the harmonic
magnitudes are given by:

Cn = 2Aav{sinc(n[pi]f/T)}{sinc(n[pi][f+d]/T)}{sinc(n[pi][r-f]/T)},

where sinc(x)= {sin(x)}/x

There seems to be a number of opportunities for a harmonic to 'hide' in
a zero of that function.

And it shows up in some math classes as well, though its main use is
in electronics. I suspect it showed up because the instructor wanted
to show a real-life example, which just happened to be -- electronics.

Great. So without a spectrum analyser there's no way to tell? If I
examine the output of the multiplier, it's very messy. There's a
dominant 3rd harmonic alright (my frequency counter resolves it
without difficulty) but the scope trace reveals a number of 'ghost
traces' of different frequencies and amplitudes co-incident with the
dominant trace. All rather confusing. I suppose the only answer is to
build Reg's band pass filter and stick it between the inverter output
and the multiplier input? <shrug>

> to crank up the B+ quite a bit.

IIRC that design called for 300 or 350 volts B+, which would work out
to 15 watts or so input. The output network is not optimized for 200
volts B+, and in addition the efficieny is better with more plate
voltage.

> Actually I don't care at this point since I am still practicing for my code
> exam, so I can't even use the transmitter right now.

What study methods are you using?
>
> How do you monitor your transmitting tone with a device like this.

Several ways:

1) Connect an audio oscillator to the key so that both it and the
transmitter are keyed at the same time. This can be a bit tricky
because the two circuits must not interact.

2) Listen to the transmitted signal on your receiver when
transmitting. This requires that you have a way of reducing the
receiver gain while transmitting, but not completely silencing the
receiver. What sort of receiver do you have to go with the
transmitter?

I've always seen it as 1/x sin(x) "one over ex sine ex". the hyperbolic sine function sinh is usually pronounced "Cinch"
So how do you pronounce sinc? "Sink ?"

Yes, it's pronounced "sink", and it's quite common in signal processing.
You define it as being the _limit_ of sin(x)/x as x -> 0 because otherwise
it's undefined at zero, and all the mathematicians in the crowd will curse
at you for being yet another engineer who's treating math so casually.

That's not precisely true.

Some fraction of us mathematicians wander away, shaking our heads and
muttering "Engineers!" under our breaths.

As others have suggested, the duty cycle may be off such that
the 5th harmonic is not as strong as it should be (it would be only
about 10% of the fundamental frequency with the 'best' duty cycle).

Part of the problem can be in trying to L-C tune logic gate outputs,
presuming a great deal that such is what you are doing. If you must
use logic gate inverters, use an open collector kind and put a 5th
harmonic parallel-tuned circuit there and couple it to a relatively high
impedance buffer amplifier input. Or, use a transistor stage and tune
the collector (or drain if FET) to the 5th harmonic.

With TTL gates the output characteristics are non-linear in that a
conducting-to-logic-0 state is a rather low impedance source while
output conducting to a logic-1 state is a medium impedance source.
The resulting loading is not good for trying to filter out a 5th or higher
harmonic. An open-collector output allows the average output Z to
be higher with less upset of a tuned circuit.

The above also applies to a series-tuned L-C circuit for the 5th but
that may be an advantage with the curious impedance of TTL gate
inputs. Using CMOS logic gates over all might prove to be an
advantage since their input impedances are quite high and most
output characteristics don't differ as much between logic 0 and 1.

>I could change the inverters for
>schmitt triggers and gain a couple of nS but can't see that making

>Would its non-linearity assist or are they only any good for even

>order harmonics?

Varactors don't create harmonics all by themselves. Those need to be "tuned" either through resonant circuits or harmonics selected via L-C filters. What you want to do can be done with stock parts but in different arrangements.

>cesium standard.

"Ordinary" quartz crystals are available off-the-shelf with tolerances
ranging from 20 ppm to 200 ppm. That equates to 0.002 to 0.020%.

TCXOs (Temperature Compensated Xtal Oscillators) will have much
better tolerance over temperature -but- the oscillator circuit itself must
be trimmed for the nominal temperature frequency.

If the operating environment temperature has a "room temperature"
range, then it might be better to use a VCXO (Voltage-Controlled
X O) enclosed in an insulated container. The voltage control (from a
very hum-free and very stable source) allows trimming down to better
than 1 ppm with the least disturbance of the temperature-insulating
properties of the enclosure...no tuning trimming shafts nor access
holes for intruding alignment tweakers needed.

There are some TCVXOs available stock at specific frequencies but
those cost a bit more than the average crystal oscillator unit. ECS
made a few of those which were dealt through DigiKey, but those
aren't in their current industrial on-line catalog.

In the NTSC TV standards, the color sub-carrier reference frequency
of 3.579454545454545... MHz is related to the 5 MHz NIST standard
frequency by: (88 x Cs) / 63 = 5 MHz, were Cs is the sub-carrier f.
Integer dividers and multipliers can create one from the other.

The NTSC aural carrier frequency offset is exactly 4.5 MHz and that
can be found from the color sub-carrier frequency by: (44 Cs)/35 =
4.5 MHz.

To compare one crystal source against another, a color sub-carrier
oscillator can be divided down by 63 to achieve 56.1818181818.. KHz
and a 5 MHz oscillator divided by 88 to get the same frequency. The
divided frequencies can be input to a phase detector whose output
can be used for direct phase comparison or for a PLL that locks one
of the oscillators to the other. Integer flip-flop dividers can be:

88 = 2 x 2 x 2 x 11 63 = 7 x 9

Reminds me of the old joke about the mathemetician, the physicist and the engineer. They were each shown into a room in the centre of which was ï¿½50 note / $100 bill (depending on which side of the pond you live).

They were told they could walk half the distance to the money and stop. Then they could walk half the remaining ditance and so on until they got the money.

The mathemetician worked out you would never reach the money so he didn't even try. The physicist, working to five decimal places was still there a week later. The engineer did three iterations, said 'That's close enough' and picked up the money.

The moral is of course, horses for courses.

Ian

The Hyperbolic Cosine is pronounced Cosh.
The Hyperbolic Sine is pronounced Shine.
The Hyperbolic Tangent is pronounced Than with a soft Th.

At least that's the way I've been doing it for the last 55 years.

They don't seem to come up very often in conversation although they are just as fundamental in mathematics as are the trigonometrical functions. They crop up all over the place especially in transmission lines where they appear in complex form such as Tanh(A+jB).

Heh heh heh...rememberances of my instructor throughout all math
classes except analytical geometry...same one, who also had
a HOBBY of advanced math. :-)

Instructor always warned everyone NOT to pronounce the apparent
word meaning hyperbolic sine...just say "hyperbolic" before "sine"
but write it "SinC." Someone in the class would object and then
he would write the word for hyperbolic tangent on the board and
challenge him to pronounce "TanH." :-)

Basic algebra texts explain what they are and their identities, but
some want to emulate Professor Higgins in "My Fair Lady"...i.e.,
"...they don't care what they DO, only that they pronounce it
correctly!" :-) :-) :-)

The inverse of the duty cycle. For a square wave 1:1 M/S = 1/2 duty
and all harmonics divisble by 2 are absent. For duty 1/5, fifth
harmonic (and multiples)are absent.

>So a 50 resistor serves as my dummy load and a meter connected to
>the dummy load indicates around 10 volts RMS. If I did my homework that
>would indicate around 2 watt output.

Uwe, The 10 Vrms that your meter indicates may not be accurate at 3.5 or 7 MHZ. It is probably OK at 60 hz. What you can derive from the 10 Vrms is that the AC-1 is producing power, just not sure how much.
One thing you might try is a method to remove the frequency dependency of your measurements. Use a 10:1 voltage divider (10k and a 1.11k). Run this thru a Germanium or Schottky detector diode and a .01 filter capacitor. You now have a DC voltage that is proportional to power, and relatively frequency independent.
To calculate the RMS voltage across the 50 ohm load: Read the DC volts out of the detector-Vdc. Then Vrms=(Vdc*.707)*10.
Example: You read 2Vdc out of the detector. Vrms=14.14 volts. Power into the 50 ohm load is then: 14.14^2/50=4 Watts. The diode drop in the dector will introduce some error at QRP levels, hopefully not too much for what you are trying to do.

>dominant trace. All rather confusing. I suppose the only answer is to
>build Reg's band pass filter and stick it between the inverter output
>and the multiplier input? <shrug>

You may want to try something like this:

```
COUNTER SCOPE COUNTER
| | |
| | |
FIN>--[50R]-+-[1N4148>]---+----+-------+--->FOUT
| |
[L] [C]
| |
GND>----------------------+----+
```

The 50 ohm resistor is the internal impedance of a function generator,
and when I set it to output a square wave at 1.5VPP, I got 10.8kHz for
the fundamental of the tank. Then I tuned the function generator down
until I got a peak out of the tank, and here's what I found:

```
Fin Fout Vout fout/fin
kHz kHz VPP
-----|-----|------|---------
10.8 10.8 0.9 1.0
3.58 10.8 0.25 3.02 ~ 3
2.14 10.8 0.2 5.05 ~ 5
```

So with a square wave in there were no even harmonics and it was easy
to trap the 3rd and 5th harmonics with a tank.

Next, I tried it with a 3VPP sine wave in and got:

```
Fin Fout Vout fout/fin
kHz kHz VPP
-----|-----|------|---------
10.8 10.8 1.3 1.0
5.39 10.8 0.9 ~ 2.0
```

2.14 10.8 0.3 5.05 ~ 5

So it looks like the second and the fifth harmonics were there. There were also some other responses farther down, but I just wanted to see primarily whether the fifth had enough amplitude to work with, and apparently it does, so I let the rest of it slide.

So, it looks like if you square up your oscillator's output to 50% duty cycle you could get the 5th harmonic without too much of a problem. If you can't, then clip the oscillator's output with a diode or make its duty cycle less than or greater than 50%, and you ought to be able to get the 5th that way.

Doug, that is much more power than I had hoped to get.
I am unsure about the max. values for the 6v6, therefore I stayed low.

When I increase the plate voltage to 325V my 2. grid runs about 280V and the plate current increases to about 65 mA. I don't really dare to do that without knowing the max values on that tube.
I guess I could lower the 2. grid voltage by increasing the value of the resistor connectd to it.
I don't know if that would lower my plate current to what you get.

And yes I have a few 807's lying around, so eventually I could build something more powerful, but at this point I need to work on my code, otherwise all of this is a mute point.

You are right about monitoring the CW, it spills over to my receiver and I can monitor it there, even if I run the transmitter with a dummy load.

So eventually I guess I could just use an arrangement that on transmitt I would automatically shorten out my receivers antenna.
Hate to use a computer chip (for example) to do it though, I will have to look for a lower tech way to accomplish this switching.

regards Uwe

Historical note: about 1960, a guy at HP was doing exactly this with some new diodes, and he got way more higher harmonics than theory predicts. To figure it out, they hooked up the just-invented HP185 sampling scope (which then used avalanche transistors to make its sampling pulses) and discovered the diode reverse-recovery snap phenom. Soon the scope itself was using this effect. They were originally called Boff diodes, after the discoverer Frank Boff, but the name didn't stick (wonder why?) and they became "snap diodes" and later "step-recovery diodes". I think I may have the HP Journal article around somewhere.

Assuming you have edges quite a bit shorter than the period, it's easy
to see what pulse widths you want to avoid to maximize the 5th: don't
let 5*pi*width/period be an integer multiple of pi. So avoid
width/period = 1/5, 2/5, 3/5 or 4/5. 2/5 and 3/5 (40% and 60%) are
not all that far from 50%. There are lots of ways to get 50% (or
close to it). One is to slow the edges a bit, and put the result into
a Schmitt trigger with adjustable DC level; the DC level will then
adjust the period. You can servo the DC level with an integrator tied
to the output and referenced to (v(high)+v(low))/2, for high accuracy.
Maybe that's too complicated, though, if you want things small. Note
that by not causing dissipation of the fundamental or other harmonics,
a multiplier can be considerably more efficient than indicated by the
percentage available power in the selected harmonic. In other words,
don't put a filter on a logic output that shorts out the fundamental,
but rather one that looks like an open circuit to the fundamental,
etc.

Cheers,
Tom

Gerry and others,
Yes I have went thru 2 of those dam things already. A big white one
with normal minute and hour hands which I threw away after a few weeks
of trying to make it behafe. Then got the more or less square shaped
one with wooden panels on eachside of the clock face. Shows
day date weekday (seconds or indoor temp) Outdoor temp. Has an ICON
top center thats supposed to show up black if WWV is being heard.
Mine rarely does unless take it upstairs and point it north/south.
Then the icon (wwv) shows very dimly. Mine is supposed to access
the WWV sig during hours from midnight to 6am only. But still the
ICON rarely shows up. I hear the people who sell them are very
helpful and will even replace your clock if you cant resolve the
problems. Their ph nr is 1 (800) 972-0292 and ask for Shelly.
Kokomo Joe (in Hawaii)

The 5th harmonic should be only 14dB below the fundamental, although it will drop fairly quickly as the sides of the input square wave deviate from vertical.

Does the 3.44MHz have a 50% duty cycle?

Are you filtering before amplifying (eg a high impedance 3 pole bandpass/highpass L-C filter with a gain of about 5 at 17.2MHz).

Does the inverter supply a decent square wave under the load of the filter?

If all else fails, could you reverse the process - generate 17.2MHz and divide it down to 3.44MHz?

(Many) years ago I made a functional TV modulator for an Apple][PC by pulling out the 3rd harmonic of the 14.318MHz system clock. I know it was only 3rd harmonic, but it was at ~43MHz, so I would expect similar or better logic should be able to produce 17.2MHz for you.

Is this a simulated circuit or a "real" one built with "real"
components?

I have at least one suggestion, but I need to know whether to send an
LTspice netlist or a gif.

Remember the harmonic energy is in the edges of the waveform. You need to
have fast rise and fall times to get the theoretical 1/5 of the fundamental.

From experience an 'ACT type device [74ACT04 or whatever] driving thru a small resistor [20 to 50 ohms] into a properly tuned tank should work. I have used that method to due a multiplication to a hifger frequency than you are looking for.

Using a "3.58 MHz" color TV crystal, it's possible to use 17 flip-flops in a set and reset depending on states of stages 4, 16, and 17 to achieve a 60, 50, or 100 Hz precise output. That's done in the old National Semiconductor MM5369 divider, a little 8-pin CMOS DIP that runs on 5 to 15 VDC single supply, crystal oscillator active circuitry on-board. If one can still find them, the following suffixes will produce the following outputs with a colorburst crystal:

MM5369AA - 60 Hz
MM5369EYR - 100 Hz
MM5369EST - 50 Hz

Couldn't find the 20+ year old notes on the division presetting so all I've got for those is a 1980 National MOS Databook (which doesn't say squat about the divider chain's details). It's an interesting game on paper with a calculator to figure out the exact division value. :-)

That little oscillator-divider was used in several Russian "Woodpecker" (over the horizon radar) blanker add-ons for receiver two decades ago.. Some additional decade dividers coming off the output would get down to the Woodpecker's impulse rate.

Forget about getting an atomic clock to set in Hawaii. The signal is
simply too weak. Atomic Time (who I bought my dual time clock from) says
that it helps if you point the antenna (apparently they just use ferrite
rod antennas-just like in a cheap transistor radio-to recieve) towards
Fort Collins, which is due east of my QTH.

Yes, that's the impression I got too. Somewhere on the net I saw a
diagram of WWVB's coverage area-it covers all of North America at night
and just a little area of the Rockies during the day.

Are you sure your not talking about wwvb, and not wwv. Or in
your case it would be wwvh.

I have watched one of my two radio clocks do precisely this - they appear to
have this iterative locking feature built in. The internal clock was first
fast two or three seconds, and the next day, slow by one or so; at the end
of a week it was right on WWV and has been ever since.

I see the sinc function all the time. I was introduced to it in school, in a signal processing class, and people at work use it fairly often. In my experience it seems that anyone who deals with signal processing or fft's is familiar with the sinc() function. And I've always heard it pronounced the same as the word "sink."

One can find out just about anything about WWVB by going to:

http://www.bldrdoc.gov/timefreq/stations/wwvb.htm

Once there, click on the yellow buttons below the photo of WWVB
towers against an awesomely forbidding dark sky. Click COVERAGE
for the best signal strength around the clock...which is 0600 to 0800
UTC. Lots of other fascinating information under those buttons,
especially on metrology of time and frequency...plus one 1.15 MB
paper from 2003 on Radio Clocks under the Publications for Time
and Frequency page.

Note: NIST must have played with their website since I was there
last in 2003. Getting to the time-frequency stations takes more
button guessing and pushing since then from the main one. :-)
I was just at the link above and it worked on 12 Mar 04.

I read in sci.electronics.design that Tim Wescott
<tim@wescottnospamdesign.com> wrote (in <105456l62pp04ad@corp.supernews.
com>) about 'Extracting the 5th Harmonic', on Fri, 12 Mar 2004:

>Yes, it's pronounced "sink", and it's quite common in signal processing.
>You define it as being the _limit_ of sin(x)/x as x -> 0 because
>otherwise it's undefined at zero, and all the mathematicians in the
>crowd will curse at you for being yet another engineer who's treating
>math so casually.

I don't fear the wrath of any mathematician. The limit is very firmly
established as = 1 at a quite elementary level. Just consider the
expansion of sin(x) = x - (x^3)/3! +.....

Of course, it can be established more rigorously, but there is nothing
wrong with the series expansion AFAIK.

Fourier (Napoleonic era or earlier?) first used his analysis to study conduction not of electric current but of of heat. That was long before the invention of the electric soldering iron. When the soldering iron (actually copper) arrived Fourier's analysis was already here to greet it.

Then along came Oliver Heaviside who turned the World upside down by replacing jw with p.

I've been waiting for someone to post this. I would only add "The drive level,
and the bais point, will vary the amount of fifth (or whichever) you will see."

It's as common as noses in RF, as Ian pointed out. Just look at the average
two-way radio prior to frequency synthesisers. Crystal freqs were multiplied
this way in transmitter chains and for receive injection, although use of fifth
wasn't especially common because you normally had enough design control to use
the more efficient *2, *3 or *4.

Interested in softwares which use the sound card for
PSK31,SSTV,RTTY,CW,HELL, ETC ETC.

Take a look at www.g3vfp.org/download.html

I try to keep up to date with most current softwares, and keep some older
stuff too.

Cheers,

Dave.

Firstly, thanks to everyone who's responded to this question. I've had plenty of valuable leads to follow up on, for which I am as ever very grateful.

It *is* actually a real one in this instance! Although I've simulated it as well, of course, but that hasn't provided any clues as to what might be causing the problem with the actual circuit.

> I have at least one suggestion, but I need to know whether to send an >LTspice netlist or a gif.

Not quite, no. Why would that make any difference? I'd have thought
any decent 'squarish wave' of the correct frequency with sharp
rise/fall edges ought to do the trick? It's spewing out the 3rd quite
nicely after all.
How about I post a pic of the sig trace into the multiplier? I'll see
if I can do that a bit later 2day...

Fifth harmonic frequency multipliers do exist, but it's usually much
easier to double and triple your way to the final frequency if possible.
(You just discovered this, I think!)

The lack of even harmonics is typical of push-pull stages ... if you
are messing around with CMOS gates, you might try using a TTL gate
(which pulls low much stronger than it pulls high) or an open collector
TTL gate, both with smmallish (100-200 ohm) pull-up resistors for
doubling.

Why not do a x3 followed by a x2 to get 17.2 MHz out of 2.866 MHz?

Tim.

As the duty cycle deviates from 50%, the even harmonics start to
appear, so you need a better filter to keep them out.

Also as you get nearer the 20-80 duty cycle the amplitude of the 5th
harmonic decreases.

Okay, I've now tweaked the osc. to get as near to 50% as possible.
Alas, still no sign of any 5th present in the multiplier's output.
Here's a shot of the (fundamental) output from the inverters. I can't
see any real problem with why it shouldn't be good for a reasonable
comb of harmonics, but our experts may know better. BTW, settings were
2V/div. and 0.1uS/div.

http://www.burridge8333.fsbusiness.co.uk/trace.gif

This other trace was snapped at the base of the transistor stage that
does the multiplying. All there is (circuitry-wise) between this trace
and the last one is a 330 ohm series resistor and a 47pF cap. I'd have
expected to see some clamping action due to the b/e junction, but the
waveshape seems very odd - but does concur with the Spice simulation.
Is there anything amiss, here? (Setting here is 0.5V/div)

http://www.burridge8333.fsbusiness.co.uk/trace2.gif

Still not a sniff of a fifth! :-(
Currently building Reg's 17.2Mhz BPF to see if that can expose it.

But one of the problems Paul seems to be having, on an ongoing basis,
is the lack of a historical perspective.

He's going the digital route because that's where he comes from, and
therefore he extends the idea. But anyone of us who have been around for
a while, or even has just spent time with older books and magazines, knows
that RF multipliers was done all the time before digital circuits had
made much inroad.

WItness the thread about VXOs a while back. He started with a digital
oscillator, again because that's all he knows, and then sets out to
pull it as much as possible. But this too has been done before, and
doing some research in older ham magazines would have shown the problems
and solutions.

Maybe "oldtimers" are biased towards what they grew up with. But I see
time after time in the sci.electronics.* hierarchy people wanting to do
RF and see it as simply extending audio or digital concepts they already know.
So they suddenly need a 5MHz oscillator, and wonder why they aren't having
success with a function generator type IC, where the needed frequency is
at it's upper limit. "How can I make an active filter at 10MHz" is not
usually someone who has a specific need for an active filter at that
frequency, but from someone who is used to active filters and has yet to
see their limitations, or maybe more importantly, are unaware of what's
normally done at RF. A coil is pretty bulky at 1KHz, but at 10MHz it's
downright easy to wind.

And I do find it interesting, to see fairly complicated answers for
problems that were solved a long time ago, simply by coming from a different
angle.

'Tune for smoke' isn't an option for most new products, which have to
be manufactured without hands.

Better to pick a suitable duty cycle (or more likely a conduction time
period in a digital circuit), that has an efficient 5th harmonic
component, including delays, at low power levels.

Here's the solution. Build a 17.2 one-transistor LC oscillator. It will easily lock to an injection of the 5th harmonic of 3.44 Mhz at any output level you like.

Whatever you do don't go for phase locked loops.

Junk your Spice. It tells you nothing you didn't already ought to know. If you don't know it then you shouldn't be doing the job anyway.

You must have plenty of room on the PCB. But why don't you invest in a 17.2 MHz quartz crystal. They're cheap enough. You've already spent more time and trouble on research and investigation. Cut your losses.

Redundency is a serious crime. It degrades reliabilty. Reliability is Quality versus Time. Every individual component must serve a recognisable, readily understandable purpose. If it's not understood then it shouldn't be there.

High Quality is adherence to the specified intended purpose.

Now I suppose some bright spark will say deliberate redundency can improve reliability. But ONLY when all else has failed.

Reg.

Certain duty cycles contain better 5th harmonic component amplitudes.
A graph of fourier components is a useful guide -

http://www.wenzel.com/pdffiles/choose.pdf

One precaution; the chart in this article does not include phase
information - this can reverse - which may be important for timing.

That waveform *has* bunches of 5th harmonic. All you need is a
properly functioning bandpass filter to pluck it out.

John

2034. TS850. Want 300mW output by use of ALC.

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-13 18:37:39 UTC
From: Rv! <no@spam.here.thanks>
Message-ID: <1079203059.26053.0@nnrp-t71-03.news.uk.clara.net>
Source record: 27870

Hi all,
I want to drive a transverter from my TS850.
I know there's a mod that's available for the rig but it is
a bit OTT as it required extensive mods.

I an thinking of building an attenuator (20dB) to take the
rig from 30w to 320mW to drive the TVTR. However I am wondering
how the ALC control might be used to help.

Will the ALC input on the radio be able to hold the radio at
300mW directly? I don't really think it will so I will probably
use the attenuator and use the ALC to hold the radio down to 30w.

Has anyone use dthe ALC dierctly on this radio? Seems it is a -V
input, but having never had to interface to this I am not sure.
Electronically I'm fine so any advice on the expected signals to
the rigs ALC would be appreciated.

I will also build a small sequencing unit to ensure the PTT is
applied nicely to the various units.

TIA..

Robert

That's close enough to 50% that you should have no problem generating
and extracting a fifth harmonic.

>This other trace was snapped at the base of the transistor stage that
>does the multiplying. All there is (circuitry-wise) between this trace

>http://www.burridge8333.fsbusiness.co.uk/trace2.gif

If you've got the cap and resistor in series with the base, and no other
circuitry in there, then what you're doing is half-wave rectifying the
square wave in the base-to-emitter diode, and that's what you're seeing,
along with what looks like some AC at the fundamental riding on the
falling peaks and rising valleys of the square wave. The reason you
can't see the fifth harmonic is because it's far enough down that
everything else is so much higher in voltage that it's essentially down
in the mud. If you want the fifth out, you'll have to extract it using
a filter of some sort, the easiest being a series tuned trap or a
parallel tuned tank.

Why don't you post your schematic so we can see exactly what you're doing?

>Still not a sniff of a fifth! :-(
>Currently building Reg's 17.2Mhz BPF to see if that can expose it.

That'll probably do it, but it needs to go on the output of the multiplier, not between the square wave generator and the input, I think.

Again, why don't you post a schematic of what you're up to? Please?-)

In a way, it IS. Fifth harmonic of an infinitely sharp transition
rectangular waveform is still low in energy compared to the
fundamental. Chances are that a single stage using an active
device as a quintupler will NOT be successful, transistor or tube
(valve).

Let's get to some specifics on this problem -

1. Let us know what you are using to determine whether or not
a 5th harmonic exists. The lack of indication may be due to
whatever it is (not a spectrum analyzer) being used.
2. Describe the multiplier stage in more detail and include an
approximate level and impedance/admittance of the RF
source. That would include supply rails and biasing.
3. Describe whatever is being used to select the 5th harmonic
and inhibit the fundamental and other harmonics. There's
lots of energy at many different frequencies floating around
there and you only want one frequency.
4. Review again with us the output drive level requirements so
we can get a handle on that.
5. If you are using an oscilloscope to measure the fundamental
waveform, estimate the actual risetime/falltime based on the
rise/fall times limits of the oscilloscope. That yields some
basic data that can be applied to a Fourier series to determine
the level of 5th harmonic energy you have to work with. [that
will also reveal the approximate frequency limits of the scope]

>>The lack of even harmonics is typical of push-pull stages ... if you
>>are messing around with CMOS gates, you might try using a TTL gate
>>(which pulls low much stronger than it pulls high) or an open collector
>>TTL gate, both with smmallish (100-200 ohm) pull-up resistors for

>
>>Why not do a x3 followed by a x2 to get 17.2 MHz out of 2.866 MHz?
>
>Because I don't have a rock lying about for that fundamental!

Hint: A mixed 2x and 3x = 5x out if filtered to pass that. No lying-around rock needed. [not an optimum solution]

Note: As already pointed out, a single PLL IC can do the job in the same PCB footprint.

When frustration hits a peak, it's time to sit back away from the problem and do an objective review of what is the overall task and what you've accomplished so far and what you know about certain circuits fundamentals. General problem descriptions only result in general solutions without quantitative values needed for a specific application.

I've found that NON-linear circuits (a multiplier stage is definietly in the non-linear category) take rather more development time than a linear circuit. There's lots of different things going on in a multiplier circuit and those have to be considered for the whole.

>Hopefully some supreme being here will spot a problem with the traces
>I've now posted...

Try as we might in the depths of our frustrations, supreme beings tend not to intervene in us humans' petty affairs. :-)

>use the more efficient *2, *3 or *4.

Fifty years ago that was mostly true and multiplier stages rarely went
beyond the 4th harmonic. Two notable exceptions, though -

A circa 1950 design by General Electric for an 1800 MHz radio relay
terminal used a SEPTUPLER via a 2C39 planar triode. [7 x multiplier]
Roughly 260 MHz input following a buffer stage from a 5th overtone
crystal oscillator. Used in both transmitter and receiver panels ("dish-
pan" style, chassis = rack panel) with the receiver septupler driving
the mixer. Fussy to tune but stayed there once tuned.

Another G.E. design of the early 1950s used Locked Oscillators in a
TV broadcast local color subcarrier supply. Locked oscillators operate

on integral multiples of the input and their use was almost extinct back then. That was deemed necessary in the G.E. design for an 11 x multiplier, the highest direct multiple I've encountered. A locked oscillator can also operate as a divider as G.E. did. The 3.58 MHz crystal could also be phase-locked to a network feed color burst.

However, all those multiplier types went the way of the dinosaur when PLLs operating directly at the desired frequency came into being. There isn't any advantage to using those old "exotic" technologies other than in restoration for nostalgia's sake.

Quintuplers CAN be made, but, so far, Paul hasn't explained enough specifics about his circuit, or how he is sensing any 5th harmonic for any of us to get a good handle on a possible aid.

Note: Lacking any spectrum analyzer, a wide-range HF receiver with an S meter can be an indicator...but such needs to be checked against a calibrated signal generator for compensation of varying S meter indication versus input levels. That's what I use for checking HF levels (Icom R70) and it has been calibrated against a reasonably-known-level RF source.

In addition to what John L. posted about adding in 4th and 6th
harmonics and making it harder to filter, if you have a 40% or 60% (or
20% or 80%) duty cycle, there will be NO fifth harmonic. From what
you've posted, that likely is the crux of your problem.

Cheers,
Tom

Hi Reg,

I'm not into cutting my losses and taking the easy way out; I wouldn't
learn anything by doing so. This circuit *ought* to work and I hope
to find out why it doesn't and remedy the situation.
I can't build a 17.2Mhz osc. I need to start much lower to multiply up
the 'pullability' of the fundamental to the best part of half a Meg.
Try doing that with a quartz xtal at 17Mhz! Sorry, I mean no offence I
know you're unaware of the background to this project.
BTW, I've built the filter your s/ware designed and it works pretty
much as advertised - bang on 17.2Mhz pass[1] and the third harmonic of
the fundamental at just over 10Mhz is *well* down by a factor of 80X
(sorry, can't be arsed to work out the dB equivalent). The coils I
used to build it were designed with one of your other programs, BTW!
Many thanks indeed. I urge anyone else reading this in r.r.a.hb to
grab Reg's programs whilst they can; they're *extremely* useful and
Reg deserves a vote of thanks from us all for taking the time and
trouble to write them.

[1] Significant spurious pass response at 13.2Mhz for some reason
(probably my use of inappropriate capacitors for the sake of
expediency - Spice didn't predict it) fortunately it just misses the
fourth harmonic!

A better place to post this would be rec.radio.amateur.antenna.

Suggest you post a bit more about how you will judge "best." That is,
what bands/frequencies do you want it to cover? Is it for receiving
or transmitting or both? What sort of listening do you want to do, or
contacts do you want to make? Clearly, there is no one "best" or
everyone would be using that. It depends on your constraints and what
you want to accomplish with it.

Cheers,
Tom

Uwe,

How are you tuning up the transmitter? Are you adjusting the plate capacitor
for minimum current?

You can count the graticule lines fairly well; it's close to 50%, and
the edges are fairly fast. And no, in fact I have terrible eyesight.

>BTW, can you recommend a sub nS Schmitt inverter that's easily
>obtainable?

I don't know of any really fast Schmitts. An HC14 followed by an AC04
should have fast edges. My favorite thing like this is an OnSemi
NL37WZ16 with all three sections in parallel. Powered from +6 or so,
it puts 5 volts into 50 ohms in something like 750 ps.

The old original RCA AC-series parts were sub-ns - crude and rude,
they were - but some ACs are now a little slower to reduce ground
bounce.

Most of the LVDS-to-TTL LVDS line receivers make damned fine
comparators with sub-ns output edges.

For screaming edges, there's always the step-recovery diode, or a medium-power gaasfet like the CLY2.

John

The crystal osc itself, probably is sine wave, and therefore has low 5th
content.
Square it up, then pass through a filter, and moderate Q parallel resonant
tank on the 5th harmonic.

There's now the schematic of the relevant stages viewable on abse. If
there's anything else that's unclear, please feel free to ask for
clarification.

Len, you're a genius! I'd totally forgotten about that old dodge. Now
I have just the job in the attic: an aging Yaesu FT767GX that hasn't
been used for years, just lying around waiting to have its front end
blown up! :-)
Thanks!

Thanks, John.
I don't see the need for anything super-fast in this instance (I mean
- 3 to4 Mhz for God's sake) but was just curious as to what they use
in UHF and beyond...
2morrow I'm going to stick Reg's 17.2Mhz BPF in line and see if that
kills the 3rd enough to allow the 5th to thrive.

As I said, since I've disposed of my SA I have no way of detecting the
presence of the 5th unless it's strong enough to be seen by 'scope or
read by my frequency counter. (Except for your brilliant idea of using
an HF rx, that is, which I intend to implement 2morrow).

> 2. Describe the multiplier stage in more detail and include an

Nothing more than what you can see in the schematic's two stages.

I prefer to go by the device's datasheet. In this case, the r/f times
are 7 to 8nS.

If there's anything I've missed out, lemme know...

Just a rough guess, since your calling on supreme beings...

That input cap... I take it the input source is a reasonable
estimate of your square wave... if the time constant of that input
RC net isn't right, it'll be a differentiator, and turn your square
wave into pulses coincident with the rising and falling edges. Your
scope trace suggested otherwise, but IIRC, at that tin=me you were
using the filter at the input to the mult., xo things have changed.

It doesn't look like you're biased in Class C. All the mults I've
seen are Class C biased with the tuned circuit on the collector. And
remember, when you're doing this later for some other purpose, in
Class C, the transistors Vceo - reverse breakdown - must be at least
twice the supply voltage.

Even worse than that - relying on simple reasoning (no maths), the 5th will be COMPLETELY suppressed when the input's rising and falling edges are spaced so they correspond in time with the SAME point in the 5th harmonic waveform, certainly at 20-80, but also at 40-60, 60-40 or 80-20 - a good reason to make sure that the 50-50 is stable and accurate.

John L. Reinartz, W1QP, published "A Fundamental-Reinforced Harmonic-Generating Circuit" in the July, 1937, issue of QST. I don't have a copy handy, but a followup article "Putting the Harmonic Generator to Work" in the April, 1938, QST contains this statement:

"It will be remembered that in the harmonic-generator circuit the crystal oscillator was operated on the crystal frequency only, and that the following tube was used to generate the even and odd harmonics up to the 11th and 12th. For our present purpose, the 8th harmonic is sufficient; that is, 28 Mc. from an 80-meter crystal...."

Hope this helps.

Nicely put.

Something like Fourier analysis can be an equation that you can apply,
or a reality you can visualize. When it becomes "simple reasoning" is
when you truly understand it.

I suppose that if a being were infinitely intelligent, it wouldn't
need any math; everything would be obvious.

Jim,

Sofar I have connected a scope to the antenna and tuned for max waveform eg.
highest voltage. That is also the setting where my dummy load with bulbs is
brightest.
The original instructions for the AC1 explain how to tune but use
expressions like 'turn the capacitor clockwise' which is useless to me when
I am not using their exact part.

They have an alternative way to tune by inserting a mA meter into the key
lead but I do not get the little dips in current they are describing. For me
it is more of a linear increase in current from the highest capacity setting
(lowest current) to the setting where the cap is all open and the current is
highest.

The way things are the max output occurs more or less at the lowest anode
current of my power supply (about 35mA at 200V B+).

Why do I tune for minimum current??

Thanks for the reply.

No, it has to be adapted to get this function. This involved adding sockets to the rear of the radio and getting access to the RF drive to the finals. Howver this isn't all that helpful in this case as the signal is apparently extremely small and not enough to drive this TVTR unit.

Page 49 of the user manual show how to convert the IF output to a low level RF drive with 250mV P-P output when drive is at max. Unfortunately this still leaves the final PA in action which is where the manual recommends connecting the transverter output (RX signal).

I don't know what their TVTR was expecting. I can get a low level drive just fine but at the same time pump the full 100w into the receive port of the TVTR. Not exactly as wanted.

Rv!

It seems as though your Plate Tuning capacitor has too little capacitance to resonate at the frequency you are using.

> The way things are the max output occurs more or less at the lowest anode
> current of my power supply (about 35mA at 200V B+).
>
> Why do I tune for minimum current??

The combination of the Plate Tuning capacitor and the inductor in the output circuit comprise a parallel-resonant tuned circuit, which has its highest impedance at resonance. Therefore, when the two are resonant, current is at its lowest point. Tuning for maximum voltage on the antenna is not guaranteed to get the plate circuit on frequency, at least not the frequency you want. On many of those older tube transmitters, there was enough range in the plate tuning capacitor that the circuit could be tuned to the second harmonic of the desired frequency. Ie, if your desired frequency was 3500 kHz, the circuit could also be tuned to 7000 kHz. Measuring antenna voltage (which many cheap rigs did, by using a "Relative Output" meter, just an rf voltmeter connected across the antenna terminal) could lead you to adjust for the wrong resonance frequency. (In the 1960s the 80-meter Novice subband was 3.7-3.75 MHz, putting the second harmonic outside of any amateur band and generating a lot of QSL cards from the FCC for unsuspecting owners of transmitters like the Knight T-60, which had only a relative output meter.)

If you can find someone who has a "dip meter," you can determine whether your plate circuit can be tuned to resonance, and, if not, how far off it is. A dip meter is an oscillator with an exposed coil, and an analog meter that dips when the oscillator is positioned near a resonant circuit. You adjust the dip meter knob until its meter dips and read the frequency off the dial. The dial calibration is not great, but if you have a general-coverage receiver you can listen for the oscillator signal.

I would also investigate the coupling capacitor from the tube plate to the ungrounded terminal of the plate tuning capacitor. It may have dried out and shorted. Carefully measure for dc voltage from the ungrounded terminal of

the plate tuning capacitor to the chassis. There shouldn't be any. If there is, replace the capacitor. As a rule of thumb, its voltage rating should be 4x the plate voltage, capacitance about 1000-1500 pF.

>twice the supply voltage.

Yup, perfectly correct. I must admit that going the class C route with
the tank tuned to the required harmonic was the way I was 'brought up'
as it were. Class C typically generates lots of harmonics as you
obviously know. This multiplier seems to be operating in class A,
which I admit is odd given its high linearity. But I didn't design the
multiplying stage you see here, but the guy who did is an RF expert so
I don't argue. :-)

But you've just given me an idea: maybe I should increase the value of
the 82 ohm base-ground resistor to increase drive signal level and tip
the stage into class C. Worth a try?

Hi all,

Following general agreement that class C might be a better bias
arrangement for the purpose of better harmonic generation, I've posted
a revised circuit to alt.binaries.schematics.electronics which makes
better use of the high input signal level available. Check it out and
let me know what you think.

The tuneup procedure (adapted to your setup) is as follows:

1) Set both output capacitors to maximum capacitance (plates fully meshed)
2) Close the key and adjust the "plate" capacitor (the one nearest the tube in
the circuit diagram) for minimum plate current. Maximum output should occur at
the same time. Release the key.
3) Unmesh the "load" capacitor about 10 degrees or so
4) Repeat Step 2. The plate current minimum should be higher and there should
be more output.
5) Repeat steps 2, 3, and 4 in order until you get maximum rated plate current

at the minimum setting of the plate capacitor.

>They have an alternative way to tune by inserting a mA meter into the key
>lead but I do not get the little dips in current they are describing.

Then there is something wrong with your output circuit. What capacitors and coil are you using? The original design had a 365 pf variable "plate" capacitor and a similar capacitor for the "load" adjustment. The coil was different for each band.

What components are you using in the output circuit? Plate tuning capacitor. coil, load capaticor, plate RF choke, coupling capacitor? Any of them could be the cause of your problem.

>For me
>it is more of a linear increase in current from the highest capacity setting

>highest.

That says to me that your plate C is too low.
>

Which should happen somewhere in the midrange of the plate capacitor adjustment.
>
>Why do I tune for minimum current??
>
Because that's when the impedance of the load circuit is closest to matching the tube's output.

That's right, but the plate tuning cap and the inductor still operate as a
parallel-resonant circuit. That's why plate current dips at resonance. In
conjunction with the loading capacitor, the pi network also serves to match
the plate impedance to the load impedance.

It is a characteristic of pi-network amplifiers that efficiency and power output are slightly better when the plate is tuned slightly off resonance. Tuning for a dip is good enough for most purposes.

> >
> >Why do I tune for minimum current??
> >
> Because that's when the impedance of the load circuit is closest to
matching
> the tube's output.

If plate voltage is 200 and plate current is 35 mA, plate impedance is 200/0.035, or 5714 ohms. The impedance of the load has nothing to do with this, it is due to the reactance at resonance of the plate tuning capacitor and the coil, which are equal but opposite in phase. You can have an open circuit on the other side of the coil and still tune for a dip in plate current. Assuming stable plate voltage it is possible to have the same plate current over a wide range of load impedances. Because the pi network looks like a lumped section of transmission line, and because the plate tuning capacitor serves the dual functions of resonating the plate circuit _and_ matching the plate circuit to the input of the pi network, variations at the load end require slight adjustments of the plate tuning capacitor. To get maximum power transfer to the load, the pi network must transform the plate impedance to the load impedance, while also resonating the plate circuit. There's more going on than simple impedance matching.

A square wave has lots of 5th and - ideally - no 4th or 6th harmonics.
Going through a class-C stage *adds* in the 4-6 guys, and then you
have to work harder to filter them out. Why do that?

C2's small size (3.3pF)is attenuating any 5th harmonic current by 6db
into
Q2's base biasing network, in both posted versions.

Biasing the first stage as classC in the second revision is a pretty
drastic change from the previous class A revision (100mW). Don't you
believe in tiny steps?

By the way, when you post a waveform where traces are only identified
by node numbers, when the schematic provided is an image only, there's
no way we can know where the traces originate, unless you tell us.

I'd shoot for a bit more than -65 dB. A good Sinclair notch duplexer
can easily exceed -95 at 600 kHz spacing. I wouldn't good for much
less than -85 dB on a two meter system.

I'm still working on an LTspice version of a varactor multiplier using
the base-emitter junction of a class C amp as the varactor. Basically using an
"idler" tank or tanks to augment the fifth harmonic.

The other idea is to make a doubler and a trippler fed from the
fundamental and then feed them into a mixer to get the fifth. If the doubler
and trippler are active (class C) stages, you should get as many db out at the
higher frequency as you put in at the fundamental. The mixer can have gain too.
Three transistors, three tuned circuits, and Bob's yer uncle.

Nah. With a *sine* input, you'd bias it so it only conducts for less
than 180 degrees of the fundamental's cycle - keep the trans *out*
of conduction for the most part. Now that I think of it, yer using a
square wave and should have the stinkin' harmonic already, duh. What
was I thinkin'? I still wonder what that input cap is doing to the
edges. The trace you posted indicates it *might* be ok if nothing

changed.

Just for grins, get rid of that input cap and do whatever with the bias to allow you to DC couple the multiplier. That's pretty class C'ish assuming a 0 - 5V square wave. Don't fry your b-e junction. Something's wiping out your 5th, so lets get that input RC outta there.

Jim, please remember the fundamental has to be in the order of
~3.5Mhz.

I suggested this a while ago, but no one seemed very keen on that
solution for some reason. Pity, as it does seem to Spice very well. A
5/6V TTL level square wave winds up as around .5 of a volt of 5th
harmonic, post-filtering. Not bad!

For the simple reason that it's dead easy to re-wire the original
board to this new config and see straight away if there's any
indication of 5th. If that should be the case, and having already
built a BPF for the 5th, the problem would be solved for very minimal
effort indeed.

2087. VCO Questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-14 23:35:56 UTC
From: Gary Morton <gary@alma.demon.co.uk>
Message-ID: <w%55c.16916$ma7.360835218@news-text.cableinet.net>
Source record: 27774

I'm experimenting with various VCO configurations/designs for a general coverage short wave receiver. The output of the VCO will drive a MOSFET mixer.

I am able to vary the gain of the oscillator. I get the best looking sine wave at the point that oscillation just starts. The 2nd harmonic is around -40dbC. The voltage as scoped at the tank is around 1V ptp. If the gain is increased the 2nd harmonic raises to -30dbC and the tank voltage to 4V ptp. I think this is about the right drive level for the MOSFET mixer (yet to be built).

Just what difference will the level of 2nd harmonic make? Does it matter whether I have -40 or -30dbC? I'm not sure what effect it will have on the performance of the final receiver, but my gut feeling is that the better the input to the mixer the less unwanted components coming out from the mixer. Then again this is not meant to be a high performance receiver.

I have seen designs which take the output from the source of the FET (for the design under test). The waveform here varies from bad to attrocious - not the kind of thing that should IMHO be fed into the mixer, although of course it will still work.

The variable gain is necessary to obtain oscillation as the tuning capacitance varies. Later I want to add an AGC circuit.

I have also experimented with buffering the tank, as this is the place with the cleanest waveform. A fet source follower didn't seem to work as expected and I now think that this type of circuit is only good for low level signals, let's say 1V ptp if the pinch voltage is around -3 or -4V. Comments?

In a previous circuit I used an emitter follower using two 100k resistors to bias the transistor base to Vdd/2. It seemed to work and certainly I understand far better the voltage swing limitations of this circuit. The tank will be loaded by <50k (depending upon beta and emitter load), however an experiment with the tank loaded with a 12k resistor showed that this had little detrimental effect on the circuit, although the gain control needed to be increased. The general opinion that I have read appears to recommended loading the tank as lightly as possible, although the advantages as not clearly spelt out (at least to me!).

regards...

Frequency stability. If the load varies it can 'pull' the oscillator. I think the output waveform will look nicer with light loading, too. Driving a diode mixer works better with square waves, which are harmonic-rich. Not sure about a MOSFET mixer.

I'm interested in your project because I just took a break from working on a design for a general-coverage receiver, using a couple of VCOs (Wadley Loop). One is going to run at ~ 55-85 MHz, the other at MF. After poring over a bunch of varactor datasheets it looks as though I can get reasonable linearity if I stick to the middle of the curve. What kind of frequency stability are you getting?

I know the Wadley Loop is pass , but I think it will be an interesting project.

Cheers,

"PM"

But I think what makes it passe is that it goes against what has
become good receiver design.

It gives you multiple conversions, when another scheme would give
you fewer (depending on design). More signficantly, there is not
much selectivity until after that third mixer. This opens things
up to mixer overload. And unless it's done well, with a good selection
of actual frequencies and good shielding, it opens up lots of
chances for spurs.

Forty to fifty years ago, the Wadley loop was a scheme that gave you
a fixed 500KHz tuning range per band, just like the Collins receivers,
but without the need for a crystal every 500KHz. Put a converter ahead
of a receiver that tunes a 500KHz range. With the Collins and all it's
crystals, you ended up with a dual-conversion receiver. With a Wadley
loop, you added an extra conversion for no reason except to replace
those crystals.

But once PLLs became commonly feasible, the Wadley Loop lost it's
advantage. You could synthesize all those needed crystals without
adding an extra conversion in the signal chain. Initially, we'd
just see synthesizers that replaced all those crystals, with

the same overall scheme of a converter ahead of a tuneable receiver.
But move ahead a few years, and the norm was to move the IF into
the HF range, and make the first (and only) local oscilaltor tuneable.
The LO would either be a premixing of a 500KHz range VFO and
a PLL that generated signals every 500KHz, or the PLL itself
would generate the LO directly, in very small steps. You still
needed to watch for good shielding and frequency selection, but
it moved it all out of the signal path.

I'd say Wadley Loops are a curiosity at this point, since other
schemes have long been available.

Of course, curiosity is always a good reason to actually try
something, and this was just a chance to comment on Wadley Loops
rather than to discourage you.

I doubt that there's any real advantage to feeding a nice clean sine wave to your MOSFET mixer -- the best distortion performance that you'll get out of the mixer will be if you're driving it hard (i.e. turning it on and off). Even with sine waves in you'd get lots of harmonics internally in the mixer.

By the way, why not use an off-the-shelf mixer like the NE602? I doubt that you'd get much better performance out of a single MOSFET unless you're a real RF circuits whiz, and the NE602 is quite easy to apply.

Good points. I'm just too lazy to learn how to design a synthesizer. I can make a Wadley Loop. I have two SW receivers now that I rarely listen to. One is a superhet, the other is a regen. At least with the regen I get to do something besides turn the tuning knob, so it gets used more often. IMO, SWBC went to hades when the Cold War ended and commercial CW virtually disappeared. As a left-wing atheist CW enthusiast (steeeerike thuree!), I don't find very much on the air that I agree with or that interests me. Maybe I should learn Spanish. :>

2092. Icom IC-251A Low Power Mod?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-15 02:22:38 UTC
From: acepilot <acepilot@bloomer.net>
Message-ID: <nn85c.361$KG2.788@reggie.win.bright.net>
Source record: 27779

Has anybody successfully modified the Icom IC-251A 2M all mode rig so that it will provide only 1 mW at the antenna terminal to drive a transverter? On the schematic, it looks like there is a plug that supplies the 13.8 Volts to the PA and driver transistors. If I removed this plug, effectively killing these stages, might there be enough power leaking through to provide the 1 mW at the antenna jack? If so, how bad do you suppose the harmonics would be at the output? Any other ideas appreciated (I could control the power using the mic gain control down to some lower power such as 1 Watt or so and then use a 30 dB pad. Down side is if I ever adjust the mic gain to 10 Watts out, I'd pump 100mW into the tranverter until the 30 dB pad finally blew)...What say???

Because a square wave has to have a particular on to off ratio to get
enough fifth. Because a square wave needs those nasty logic gates. Because
three transistors are simpler.

3.5 MHz... 3.5 GHz 3.5 uHz... makes no difference. The laws of physics
scale nicely for most electronic circuits. Although some ICs are getting
features small enough that the electrons have to line up single file. 8-)

I assume that this is an up conversion design, with the (first) IF
well above the intended Rx band.

>The output of the VCO will drive a MOSFET mixer.

I assume this is a single ended dual-gate MOSFET mixer (and not some
kind of MOSFET quad).

In dual gate MOSFET mixers (as well as in heptode mixers) the load
current is proportional to both the gate voltages, thus some
multiplication occurs between the various gate signals and the
trigonometric relation sin(A)*sin(B) = 1/2*(cos(A-B)-cos(A+B)) can be
used to estimate the amplitudes of the mixing products.

>is about the right drive level for the MOSFET mixer (yet to be built).

The second and higher harmonics will no doubt produce mixing products
with the antenna spectrum and will cause a lot of unwanted responses
at 2LO+/-IF and 3LO+/-IF and so on, but this is mainly a problem, if
the IF is comparable to the received signal (e.g. 9 MHz or 10.7 MHz)
or the LO is below the received signal, in which case the second
harmonic could fall close to the received frequency. In all these
cases, it is important, that there is a sufficient selectivity in
front of the mixer, usually requiring at least one and preferably
several constantly tunable front end stages as in high quality old
receivers.

However, in up-converting systems, with say 40 MHz IF, the LO range is
40-70 MHz, the second harmonic is 80-140 MHz and the unwanted signals
that can produce the 40 MHz IF signal are at 40-180 MHz. Good
shielding and a steep fixed low pass filter at 30 MHz should take care
of these higher image responses.

While the unwanted mixing products may still occur, the mixing is
between the internally generated front end thermal noise and the 2LO,
the amplitudes are insignificant, especially when receiving the noisy
HF range.

If you are using the traditional general coverage up-conversion system, I would not be too concerned about the amplitude of the second harmonic.

One advantage of using some balanced, hard driven mixer, is that the first strong spurious response is at 3LO, the spurious image responses are at even higher frequencies, simplifying the input filtering.

The reactance of the C2 part is almost 3K at the fifth harmonic.

Input impedance of the biasing network is 300 ohms - this is about
half the small signal input impedance of the 3904 @4mA.

Even with bypassed emitter, only 1/3 of C2's AC current will enter the
base of Q2.

If the resonant circuit used lower L and higher C values, C2 could be
increased without as severe an effect as it has here.

> days. There's no harm in the ocassional quantum jump. :-)

As previous posters have stated, if the input is squarish then the
harmonics are already there.

There is a +/- 3% window on all the optimum duty cycles (ie 10, 30,
50, 70, 90%), including risetime, for which the 5th harmonic amplitude
is relatively constant, at about 10% of the initial peak amplitude.
Note that the 30/70% period is a median quasi-minima for both 3rd and
4th harmonics, possibly reducing LF filtering problems in the first
stage, as the 1st and 2nd are farther away. 50% being available, you
should stick to it.

I don't know if you're doing any actual physical breadboarding. The
100mW power dissipation suggests not. Pre-apps it's time.

If this is a physical breadboard, then perhaps you might let us know what you are actually using for your 2uH inductors. You wouldn't want the relatively hefty classA bias to have any effect on them, so there should be a lot of air in their flux path - not a couple of turns on a bead, I hope.

> Thanks
> John
> MW1FGQ

Are you sure its 33123A , and not 33132A ?

I found 33132A in catalogue from late 70:th tells that you can find info
how to drive them in: HP application Notes 922, "Applications of PIN Diodes",
"Selection and Use of Microwave Diode Switches and Limiters"

I dont have that app. note but the old catalogue tells under Driving Consid.:
Driver requirements are dictated by the specific application.
When the switch is used as a modulator or attenuator, a current amplifier is
required. Suitable integrated circuits can be obtained for either laboratory
or OEM applications.
Typical 10%-90% switching speed is 50 to 100 ns in either of-on or on-off
switching.

2099. 100W linear PA: output matching

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-15 09:51:31 UTC
From: Heikki Ahola <heikki.ahola@vtt.fi>
Message-ID: <40557CA3.D34DEDED@vtt.fi>
Source record: 27786

Hi!

I am planning to increase my RF output considerably beyond the QRP levels I have been using thus far. The idea is to construct a 100 W PA-module with IRF510-fets
as many others have done before... At this stage I will concentrate in the 160, 80 and maybe 40 m because the switching fets may not work too well at higher frequencies and also I feel that this extra power is most urgently needed in the lowest bands.

For this power level two pairs of IRF510 are needed in push-pull configuration and with Vdd = 30 V. The question that has bothered me is the type of output matching.In order to reach the 100W level an impedance step-up 1:4 is necessary. After studying ARRL HB:s from the past decades, RSGB material and Solid State Desing for Radio Amateurs I have noticed that a conventional broadband transformer with two rows of ferrite toroids is used almost invariably. In some cases like the 300W design by the late H. Granberg (from Motorola) a transmission line transformer wound on two separate toroids is used. What is missing totally (in this power level, at least) is the application of large single toroids as transformers (why ???).

Another possibility which might be feasible is a narrowband (T-) matching section for each band (max 3) followed by the standard low pass filter.

Any comments/suggestions from more experienced homebrewers ? Also, if a better but still low cost alternative for IFR510 has appeared in the market, this info also taken into consideration when finalizing the design...

Understood. I chose a very low value for C2 because it was the third harmonic that was dominating and most needed cutting down to size. Though the reactance at the fifth is high, it's a lot higher still at the third. Although I suppose I could have used a simple series L/C tuned circuit tuned to pass on the fifth and attenuate everything else. Do you think that might work?

>If the resonant circuit used lower L and higher C values, C2 could be

Good point.

I'm as close to 50% as I can get. If square waves are so finicky about producing the 5th if their mark/space ratios are a tiny bit out then maybe I need to consider some other way of generating such harmonics.

>I don't know if you're doing any actual physical breadboarding. The

I'm using my 'leopardboard' technique: a layer of PCB with liittle island pads etched out in copper and component ends soldered to those islands.

Hi all,

I've got quite a huge stash of inductors in my parts bin. The colour codes don't always seem to relate to the values I've been able to measure, with my multi-function DVM, however, and I can't accurately measure any inductor < about 10uH. Is there a circuit anywhere that would enable me to get a reasonably accurate idea of the values I've got down to say 100nH or thereabouts?

Thanks,

p.

If you have a signal generator you can connect them to a suitable capacitor
and measure the resonant frequency.

Nyuk, nyuk, nyuk. I bet if he had a signal generator, he wouldn't be
looking for inductors to shotgun that multiplier :) In fact, he
wouln't even be building a multiplier.

The reason no-one seemed keen is that the OP's **complaint** was that
his 5th harmonic BP filter didn't produce any output.

I think we have to supplement 'Read The Fascinating Manual' with 'RTCT'
- 'Read The Copulating Thread'.

So I guess Fourier was wrong; makes sense, with a French name like
that. Somebody in this group also proved Shannon to be wrong... does
anybody remember who?

John

That would be my concern: Just how much other "crap" would be
"leaking through" at or around the 1mW level.

I do have the IC-251A, but I've not had the need to do what you
are attempting ------ yet.

No, what has emerged from the discussion is that rather small deviations
from a perfect square waveform can drastically reduce the amount of one
or more harmonics in the spectrum, and this probably is the source of
the problem.

This has been answered fairly often here before. You might try a search. The AADE L/C Meter II does quite an adequate job down into the nanohenry region, very quickly, for excitation at a few hundred kHz, and for relatively little cost. For better info at specific operating frequencies, try a vector network analyzer such as the N2PK one I believe you already know about.

The VCO operates over a wide range, making the control of such a filter quite tricky. There will be three ranges and this would add to the complexity.

I built a short wave receiver many years ago. The design was from a Babani Press book (highly recommended). It worked OK, but I always hated not knowing the exact frequency. At the time I had no tools to even calibrate the dial.

The front end was a single transistor oscillator and mixer. I tried the "improved" design which used a MOSFET, but I didn't have the right Denco coil and the performance was degraded.

The intention is to add digital tuning to this old project.

What???

According to your schematic, the input to R1 is a 2.16MHz square wave
and L1VC1 is a parallel tuned tank, (filter) tuned to 10.8MHz. So is
L2VC2C7. If you're not trying to do any filtering, what are those tanks
doing in there?

That is the nature of oscillators. As you then increase the gain, the amplitude increases until some non-linearity prevents it - usually the available voltage swing in a device. This non-linearity causes the harmonic content to appear and rise to fairly significant levels, as you have observed.

Whether the harmonic levels you noted are of great significance depends on the mixer attributes.

One technique often used is to ensure the limiting non-linearity occurs in a separate gain stage following the oscillator. Gain control derived from that stage is then fed back to the oscillator to keep it in that "just oscillating" region where harmonic content is lowest. A separate take-off from the oscillator through a second buffer stage is then used as the actual output.

In my humble opinion,
Oops, sorry ;)
Anyway...
I thought of Plan B today while sitting on the crapper (or is that the "Engineering Bench" ???). I'm thinking of adding a large resistor in series with the top side of the MIC GAIN pot, something like 470K to 10M, determined experimentally, so that the 10K pot, when at fully clockwise position would only provide enough audio to the modulator to make 1 mW out to the antenna jack (simple voltage divider). I don't want to fry a $300 transverter by forgetting to turn the Mic Gain down =:O (which I KNOW I would do at some point -- like portable operation in the USA's rarest grid square, where I'll be for the June VHFQSO Contest)

Source record: 27672

Personally, I prefer to use a square wave, or at least a strong sine wave into any mixer....

The mixer itself is non-linear and so it will usually produce a number of LO harmonics.

Driving the LO at a high level reduces the length of time the mixer is in the 'semi-on/off' region as the LO transits through 0 VAC.

Generally speaking, that time near 0 VAC LO is where the mixer is most prone to being overloaded and intermod products being created so a strong LO drive usually results in somewhat better dynamic range for the mixer.

I plan on the filters before the mixer to keep signals at the LO harminoc out of the mixer, and as noted in another posting, a simple lowpass will do the trick in an upconverting Rx design.

Collins plate transformer part number 672-0531-009
Rated 115-230VAC 50/60Hz in, 2250VCT at 565ma out.
No load: 115V in, 2580VAC out - 120V in, 2700VAC out.
Black, hermetically sealed, ceramic post terminals.
5 x 5.5 x 6.5H, 26LB, used, looks and works fine.
$75 pickup, plus actual UPS shipping

NIB Triad A-35A 10K plate to 90KCT single or P-P grids.
Unused. Allied catalog says freq response 50 to 10K.
2 x 2 x 2.5H inches. $24

2 each NOS Stancor WF-30 multi-Z interstage AF xfmrs.
Hermetically sealed. 1.5 x 1.5 x 2H inches. $5 ea

---coax relays---
These are Danbury-Knudsen or FXR, silver-plated, flat to 600MHz+,
100W+, BNC coax jacks. See old Allied/Newark catalogs.

FXR, NOS, SPDT, 115VAC coil, 2 x 1.5 x 1 inches, $13

D-K, used, SPDT, 18-24VDC coil, 2 x 1.5 x 1 inches, $13

D-K, used, SPDT, 12VDC coil, 2 x 1.5 x 1 inches $13

D-K, used, SP6T, 12VDC coils, 3 x 3 x 2 inches, $23

Motorola, NOS, SPDT, 6VDC coil, 3 x 2.5 x 1.5,
Ant and Rx BNC, Tx solder terminal, $12

---filters---
Stock HW/SB CW filter
Part no. Model no. Type Bandpass6/60 Used on
404-284-1 SBA-301-2 CW 400 Hz/2 kHz HW/SB 100/101/102
$40

Stock Drake 4-line C-F Networks xtal filter model 5645-2.4L
with carrier xtal 5644.999KHz. $30

---xtals---
38.1MHz xtal for Drake 4-line. $3

1 lot of 5 HC-6 xtals. 3.4, 10.4, 17.4, 23.4, 24.4MHz
$16

1 lot of 4 HC-6 xtals. 1.545, 4.545, 15.545, 22.545MHz
$14

Allison has touched all the important bases - his suggestion is the best way to do it.

The idea of just pulling the plug will not work - you'll turn all the power devices into passive diode limiters, and if anything comes out at all, it will be filthy. Likewise the huge reduction in audio drive will not work, because the SSB/CW signal will drop down into the circuit noise, and probably well below the level of the not-quite-suppressed carrier.

For a complete solution, install a little RF relay to switch the drive signal to an output socket on the rear of the transceiver. As Allison says, do this *after* the filters at the operating frequency, just before the signal enters the driver/PA boards. Also install a DC power relay to remove the supply to those RF power stages. Wire the two relays so that when they are not energized, the transceiver works as normal.

The deluxe - and safe - way to control those relays is to supply 12V DC down the coax cable between the new output socket and the transverter (using RF chokes and blocking capacitors to separate the DC from the RF at each end). When the transverter is powered-on, it commands the transceiver to send it low power. When the transverter is off, the transceiver simply goes back to normal.

You don't know exactly what power level the driver stages will provide. If it's too high, attenuate it. If it's too low, use an MMIC amp. If - as seems very likely - the transverter comes from Down East Microwave,

the facilities you need will probably be on-board.

As Allison says, use a separate route for RX input. This will require yet another small RF relay (powered the same way as the others) but it will make sure you can never empty the full transceiver power into the RX output of the transverter.

This system with DC control down the low-level TX coax will take a little time to install, but it is highly reliable and very safe. I've used it on a number of rigs here over the past 20+ years, and it has never let me down.

Hi,

> To save $100, I'm not going to copy *anybody's* circuits.

An unfortunate choice of words on my part perhaps; possibly 'copy his technique' would have been better. A technique, I should add, that has been in the public domain for a very long time. The basic idea being -

1. Take an oscillator tank circuit with fixed C1 or L1.

2. Measure frequency F1.

3. Connect unknown Cx across C1 or Lx in series with L1.

4. Measure new frequency F2.

5. Calculate Cx (Lx) using a scientific calculator, remembering that F2/F1 = sqrt(C1 + Cx) or sqrt(L1 + Lx) then we have,

Cx = C1([F1/F2]^2 - 1) or Lx = L1([F2/F1]^2 - 1).

For best accuracy you would need to know the value of the strays which may easily be worked out using the same technique in reverse, or swamped, as the fancy takes you.

On the subject of copying, I would guess that 95% of homebrew projects rely on pre-published information; there must have been hundreds of 'chinese copies' of commercial rigs produced by hams over the years. And it goes without saying that homebrewing not buying is what we are supposed to be talking about in this group.

Cheers - Joe

OOPS!!

5. should have read -

Calculate Cx (Lx) using a scientific calculator,
remembering that F2/F1 = sqrt([C1 + Cx]/C1)

or sqrt([L1 + Lx]/L1) thus we have,

Cx = C1([F1/F2]^2 - 1) or Lx = L1([F2/F1]^2 - 1).

Cheers - Joe

Ian,
Thanks for the pointers! I could delete the relays since I am going to dedicate the IC-251A to low power service on a permanent basis. I bought the rig specifically to be used with transverters. I have a much newer rig that covers 2M (Yaesu FT-857) and it puts out 50 Watts instead of only 10 Watts like the IC-251A.

Now it's just a matter of where to "pick off" that low level RF. I have it narrowed down to Q30 (pre-driver), but there is so much circuitry (coils and caps) between it's collector and the next stage's base lead. Do you think I could just remove the driver stage (Q31) and solder the center lead of a piece of coax, say RG-174, into the now empty base lead hole and bring it out the back of the rig? Is any sort of impedance matching required?

The plan is to use this to drive the Down East Microwave series of transverters, so harmonics may not be a real big issue since I believe they have pretty tight filtering at their design frequencies that would greatly attenuate the next "spur" 144 MHz above the desired output (i.e. 1440 MHz for the 1296 transverter)...

Any final thoughts???

Errr... I read the thread. And in your first message you say. "All I
can get apart from the fundamental is a strong third harmonic on 10.32Mhz,
regardless of what I tune for. I've tried passing the osc output through two
successive inverter gates to sharpen it up, but still nothing beyond the third
appears after tuned amplification for the fifth."

If I'm not mistaken, "tuned amplification" IS "filtering".

Jim

OK, that's fine. You can easily make the modifications reversible in
case you might want to sell the rig.

There you've lost me... I don't know the circuit details of that rig,
but at these very low levels it might well work without re-matching.

That's correct. The level of the 1440MHz spur is mostly determined by
how hard you drive the mixer with the main 144MHz signal, and very
little by that signal's own harmonic content (unless of course it's
gross, which there is no reason to expect - the big harmonic generators
are the high-level stages that you won't be using).

>doing in there?

The frequency of the square wave is actually 3.43Mhz (IIRC) the figure
you quote from the schematic is the *period.* Plus, the tanks are
actually shown tuned to 18.75Mhz (well the first one is, anyway, but
since they're variable caps they can be tweaked for the desired
frequency of 17.2Mhz. I've no idea how you've arrived at 10.8Mhz!
Yes, I realise tanks are a form of filter hence in prior postings I've
stated I'd not used any form of filtering *other than* the tanks.

That's more macaroni than even *this* eyetalian can eat.

You're confusing me again. If you have a filter on a bot in the
field, it's the same filter that was on the bot before you got there
and should do the same thing.

If you change a filter in the field, you'd want to sweep it before
it's installed in der bot.

An argument over semantics, then. AFAIC it's not filtering as such.
It introduces a high degree of selectivity, certainly. But when
someone says "filtering" I assume they're taking about a pi-network or
something of that sort, between stages or at the end of a chain of
stages.

You need to read up on active filters, and when you've done that, you should
read a book on digital filtering.

Source record: 27688

The performance of a single-transistor pulse (harmonic)-generator is covered in program HARM_GEN now available from website below in a few seconds. Easy to run.

The manner in which the amplitude of the harmonics 1 to 30 vary with frequency and with operating angle (pulse width) are shown.

In general, with a very short pulse width, as the harmonic number increases, the output level falls fairly uniformly. But as pulse width (operating angle) increases then some harmonics almost disappear from the spectrum. The program displays harmonic levels in decibels.

Fourier, that great French mathematician/philosopher wuz right! I think he missed Madame guillotine.

Download program HARM_GEN now. It might be useful one day.

FWIW, just now I had not trouble at all filtering the fifth out of a square wave, in exactly the way I suggest below. It seems very silly to me to put nonlinear elements in when you already have plenty of the harmonic you want. I don't know what logic family you're using, but if it's a modern one like 74AC, you should have several milliwatts of fifth harmonic available. A simple series resonant LC from the logic output to the base of a 2N2219-type transistor should get you at least a couple mA RMS of fifth harmonic base current, assuming a grounded-emitter stage with roughly 50 ohms input resistance. Make the loaded Q of the LC something around 10 to 20, and you won't screw up the amplifier with other harmonics or the fundamental. Be a bit careful about the coil you use, because it will be fairly high inductance for the frequency you're interested in...that is, keep the unloaded Q and the self-resonant frequency high enough. Use another moderate-Q tank in the collector circuit; you should be able to get over 100mW of fifth, with other harmonics down 40dB or more. You can get more complicated with the filtering if it's necessary, but for fixed-frequency operation, there's nothing wrong with simple synchronous tuning of single resonators set to reasonably high Q. If you insist on using the unnecessary complication of a multi-pole bandpass filter, be sure the one from the square wave to the amplifier starts with a series resonator, not a shunt resonator.

Sheesh...all you need to do is selectively amplify the harmonic you want; it's already there. Don't add complexity trying to generate something you already have in abundance.

Wow - the strange things you learn on this thread! So how many poles does a
circuit need for it to be called a "filter"?

"splat" test

V=L*dI/dt

charge up a large cap to some voltage V

short the cap thru the inductor, and measure the current with a scope (digital is great, as long as the single-shot sample rate is high enough - I did this once with an HP 56000 series scope, and got 1 data point - very easy to fit a line to, very hard to fit the right line to!)

knowing dI/dt and V, calculate L

then, you can see saturation from where dI/dt increases rapidly (invaluable for power electronics)

also, ensure that 0.5CV^2 >> 0.5LI^2 at the current of interest - this ensures that V is approximately constant

I have a couple of 33mF 35V caps in parallel, with 10 x 1R MRS25 resistors paralleled as a current sensor. It takes about 45s to set up for a measurement. I often use the shaft of a screwdriver to make the "splat" - a nice hard material is good.

I have used this technique successfully to measure inductors ranging from the tiny (< 500nH) to huge (3mH 2,000A chokes). Actually, big chokes tend not to read true on LCR meters, as the magnetic material permeability is often much higher at very low currents - especially true of iron powder.

if you dont have a digital scope, make a tiny, LF oscillator with a 555. Drive a grunty FET, with a small (I use 0.1R - 10R) source resistor. Then, you'll get a repetitive waveform, which works nicely on any analogue scope. If Rsense is nice and low, use a 50R BNC cable to connect to scope, with a 50R terminator at the scope - lovely clean waveforms.

I built a little tester like this to test air gaps in planar cores for a 55W smps that lives inside an LED video screen (actually, thousands of them live inside). works a treat, and cost < $5.

One of my techs once built a splat tester for big chokes - he had several 1200V 600A IGBT's in parallel running as a series pass regulator, with about 100mF of capacitance (charged to 700Vdc thru several lightbulbs) to control V, even at currents on the order of 5,000A. A honking great LEM DCCT measured the current, and the "switch" was purely mechanical - he used the pole faces from an HV contactor, as the material is astonishingly arc resistant, so no pitting/welding

Any network which exhibits frequency selectivity is a filter, whether or
not you're concerned about whether or not it is or is not.

Think about it... from the lowly filter capacitor to the exalted
brickwall filter, they're all discrimating against a frequency or a set
of frequencies which we have told them we don't want them to let us see.

Filters, every one.

Just for grins, take a little trip over to a.b.s.e. (same subject
heading)and take a look at what John Larkin's series resonant filter
feeding a parallel resonant filter strategy looks like as far as
allowing you to get a fifth harmonic from a fundamental square wave
goes.

That's just a standard bandpass. What you do is pick a normalized
lowpass filter that has the response shape you like, say a Tchebychev
(I know... various spellings) and scale it to the impedance Z' and
bandwidth W' you want. Then series resonate each L with a C, and
parallel resonate each C with an L, both at some desired center
frequency. Voila (pardon my French) a bandpass that's 2W' wide.

There's no real reason to cascade lossy Q-killing tuned transistor
stages when you can put all your Ls and Cs in one place.

Message-ID: <20040317020221.05957.00001034@mb-m26.aol.com>
Source record: 27697

For a comparison of rectangular waveform on-times versus spectral
content, the following calculations were done on my WAVESPEC
program for a 0.50 to 0.25 times repetition period and with rise and
fall times equal to 0.02 times repetition period.

If the fundamental energy is the reference, then the harmonics
are down from that 0 db by the values shown:

```
/------------ width rel. to rep. period -==---------\
Harm 0.50 0.45 0.40 0.35 0.30 0.25
1 0 0 0 0 0 0
3 -6.4 -7.3 -8.4 -9.6 -11.1 -12.8
5 -28.0 -17.8 -15.1 -15.7 -20.3 *
7 -28.1 -20.1 -26.2 -27.7 -26.6 -29.1
9 -28.4 -24.6 -32.1 -44.2 -43.0 *
11 -28.7 -32.7 -42.2 -25.1 -35.8 -28.7
13 -29.1 * -29.1 * -29.1 *
```

* too far down to matter, not enough there

The above will hold true at any fundamental frequency provided the
rise and fall times are equal and each equal to 0.02 times the
repetition period. Those numbers will change given faster or slower
rise/fall times. All db calculated as 20 x Log (voltage). Width is
determined at the baseline, not the 50% amplitude point.

Hi,

> Fourier, that great French mathematician/philosopher wuz right! I think he
> missed Madame guillotine.

Yes, he died in Paris in 1830. He was an active revolutionary but fell foul of the powers that be and was imprisoned for a short time. Fortunately for him they topped Robespierre first and he was released when the politics changed as a result. As he wasn't into electric phenomena, he wouldn't have realised the uses that the offshoot of his theory on the conduction of heat in solids (Fourier Series) would be put to in later years. So the next time you burn yourself, while holding a piece of wire you're in the act of soldering, you will know who to blame.

Cheers - Joe

Okay, well at least I can see this one! Not sure about the SA trace,
though. Came out clearly enough but I'm not sure what you were trying
to prove by it. As for the 'scope traces, there doesn't seem to be any
phase correlation between the two and you don't indicate at what point
the probe was inserted. The square wave r/f slopes look a bit tardy,
too. What was the active device you used to generate them?

It's basically the same type as Reg's program designed for me. That
was built on Sunday, tested and found to be bang on the money and
later today I shall try to see if it can be used to 'extract' the
elusive 5th. I have to admit I'll be surprised if there's nothing
there at all, but we'll have to wait and see. Don't touch that dial!

Hi,

They look worryingly inductive on visual inspection (there are metal foils rolled up in thar by the look of it.) And yet the CPC catalogue says that their properties make them ideal for use in filters. Has anyone any remarks (favourable or otherwise) to make about the use of this type of cap in filter apps?

p.

Hi Paul!

There are non-inductively wound ones specifically for the purpose. The mfr. specs should show an ESR curve - the non-inductive ones are pretty flat to their SRF.

They are OK for LF filters, the inductance won't make any appreciable
difference and they are available with 1% tolerance. They are getting
difficult to find. They are also useful for RF oscillators.

It's an FFT of what's coming out of Larkin's suggested two-stage
bandpass filter.

The first vertical marker (f1) goes through the first peak, 17.19MHz,
which proves the fifth is in a 3.44MHz square wave. The second marker
goes through 34.38, so so's the tenth.

> As for the 'scope traces, there doesn't seem to be any
>phase correlation between the two and you don't indicate at what point
>the probe was inserted.

Are you kidding? Count the high frequency cycles between the first
leading edge and the same point on the second leading edge of the square
wave and you'll find there are exactly five.

>The square wave r/f slopes look a bit tardy,
>too.

That's because the generator wasn't isolated from the filter and you're
seeing the filter's input dragging it around.

>What was the active device you used to generate them?

Tektronics FG502. Here's the layout:

```
[TEK FG502]-+-[BPF]-+-[TEK 2465A]---[HP5328A]
| |
| +-[HP54602B]
|
[TEK DC504]
```

Curious that there should be a sizeable pass response at the tenth
harmonic, isn't it? It doesn't appear to be *that* much down on the
intended pass frequency although there appears to be no indexing for
the y axis.

Well, I admit I'm a bit of a greenhorn on these things, but to my eyes
there appears to be some phase difference. I'll accept your word for
it there isn't.

I notice some of them come with one end tinted red (or sometimes
black). Does this indicate the non inductively-wound type?

The topic is WWVB, the binary signal. WWVH is the voice signal, which an autosetting clock will not understand.

That may be the case Scott, but the 'atomic clocks' they are speaking of use
the WWVB signal from Ft. Collins, Colorado on 60 KHz to set their time
automatically.

That signal may indeed not be propagating well enough to be of use in Hawaii.

I agree with whoever said WWVH in Hawii is l/c and on same status
as wwv in Colorado, so these "skyscan" clocks should perform as
specified. I found though that my latest one will keep time
right to the second for a period of time, the I have to move it upstairs
where reception is better and leave it there for 24 hours. Once
reset to exact time tick I again put downstairs in the shack and its
good for another momth or so. I fail to see how the clock reader
can discriminate between WWVH (on Kauai) and WWV in Colorado.

But most atomic clocks use WWVB on 60 khz out of Fort Collins. WWVH, to
my knowledge, only uses HF freqs (5, 10, 15 Mhz). But yeah, I'm sure the
rice keeps better time than the people who eat it. :)

I heard the LuaLuaLei transmitter a lot, but not WWVH, when I lived there.
500kW or 1MW IIRC, somewhere around 24kHz.

Yup. Take two sheets of letter-size (okay, A4) paper and lay one on
top of the other but the top one to the right by 1/2". These are like
the plates of your capacitor. Now roll them up from the bottom to the
top into a tight roll. Imagine you connect to all the right end (in
parallel) by dipping it in some conductive goop, and call that lead A.
Do the same to the left, and call it lead B. The coiled construction
adds no inductance.

Yeah, they're rolled up, but the contact is made across the ends,
generally, not just at one location in the roll. (That's why you
should build that vector network analyzer...) But I'd avoid them:
they can't take the heat. C0G ceramics and polyprops are both good.
C0G ceramics are available up to 10nF or so even in SMT; polyprops
down to 1nF at least and up to many uF.

Cheers,
Tom

Gary, you may be right regarding my power output measurement, but I thought
I knew how you calculate DC power and AC power of sinusoidial waveforms on
my scope, which, by multiplying with 0.707 you have to reduce first to the
aquivalent of a DC voltage.

What confuses me in your suggestion (printed below) is that even after you
rectify an AC signal and send it through a filter capacitor you STILL
suggest to multiply it times 0.707.
I would have thought that would give you the wrong result??

Where do I go wrong, if at all??

I thought WWVH also had BCD data a couple times an hour? Or has that been
stopped along with the Omega navigation beacons?

Is there no VLF facility in Hawaii comparable to WWVB?

The data sent on 60 kHz by WWVB isn't transmitted by WWVH. Here's a
chart of the coverage areas of WWVB and it looks like it has a decent
chance of being received in KH6-land at certain hours, like 0800 UTC.

WWVH is the 2.5, 5, 10, 15, and 20 MHz voice and data transmitter, it's on
exactly the same freq as WWV in Ft Collins. If you listen, there's a
silence before the guy on WWV speaks, that's for the lady from WWVH to talk
first. (very polite :)

The clocks use WWVB which is a 60 khz signal.
Interference from LuaLuaLei may make that impossible to pick up.
There also used to be a Loran transmitter around 100kHz IIRC, on the north
shore of Oahu, but they may have taken that down now.

2189. Re: Polystyrene capacitors for filter networks?

>this type of cap in filter apps?

BIG difference between two types of rolled-foil style or "tubular"
capacitors even at MF. For MF or even LF, use the low-inductance
"extended foil" type; manufacturers will indicate that difference on
datasheets, catalog listings.

Extended-foil construction offsets the layering so that one foil
overlaps the insulating film or paper at one end, the other foil
overlapping the other end. When axial leads are attached, the
foil overlaps is crimped down on the lead so that nearly all turns
of the foil at one end contact the lead. Minimum inductance.

Conventional old style of construction had the two foils neatly
aligned with no foil protruding from the wider insulating layers.
Axial leads were then clamped at only one end of the foil wrap
end (usually the finish end) and the result had a fair amount of
residual inductance in the remainder of the foil wrapping.

A few makers introduced deliberately series-resonant bypass
tubulars many years ago, intended for the ubiquitous 455 KHz
IF amplifier stage bypassing. Broad series resonance but it
worked (sort of). Rather a rare tubular now. Curiosity.

>can discriminate between WWVH (on Kauai) and WWV in Colorado.

The answer on "discrimination" is on the NIST time-frequency pages.
The "tick" from WWV in Colorado is 6 cycles of a 1 KHz sine; the
"tick" from WWVH is 5 cycles of a 1.2 KHz sine.

Scoping a receiver detector output will show that. Looks unusual
when somewhere in between Hawaii and Colorado and propagation
makes both about the same strength. :-)

In the ancient times of prehistory, circa 1955 or so, many TV
broadcast stations did a time-sync of station clocks from the fixed
tone onset from WWV...either there or not there and the periodicity
of the background tone was very predictable. WREX-TV did that
in the midwest when I worked there in 1956. Thought that they
would have done it much fancier ways but that albeit crude way
worked out very well to keep station clocks within a second.
[Time is the income commodity of all commercial broadcast
stations and muy importante]

I'm not familiar with the old Heathkit "Most Accurate Clock" for use
on HF at 5, 10, 15 MHz. Someone else can comment on their
discrimination circuits (if any).

>
>I wonder what happens to these numbers as the rise/fall time tends to
>zero?

The harmonic content will increase...but also show dips depending
on the percentage width relative to the period. I could present those
(takes only minutes to run the program and transcribe the results)
but that is academic only. The rise and fall times will NOT be zero
due to the repetition frequency being high (repetition time short).

Consider that a 3 MHz waveform has a period of 333 1/3 nSec and
that Paul is using a TTL family inverter to make the square wave.
Even with a Schmitt trigger inverter the t_r and t_f are going to be
finite, possibly 15 nSec with a fast device (and some capacitive
loading or semi-resonant whatever to mess with on- and off-times).

15 nSec is 4.5% of the repetition period, quite finite...more than I
showed on the small table given previously.

I'm sure someone out there wants to argue minutae on numbers but
what is being discussed is a squarish waveform with a repetition
frequency in the low HF range. Periods are valued in nanoSeconds
and the on/off times of squaring devices are ALSO in nanoSeconds.
There's just NOT going to be any sort of "zero" on/off times with
practical logic devices used by hobbyists.

What is not intuitive to me (and to others) is that harmonic energy
of a rectangular waveform drops drastically by the 5th harmonic
and is certainly lower than "obvious" numbers bandied about.

But, also mentioned before by others is that shortening the rect-
angular waveshape DOES increase the 5th harmonic, as evident
by the approximate 12 db increase at 40 to 35 percent of the
repetition period.

An equivalent shortening happens in vacuum tube multipliers through biasing (self, fixed, or both) and that can be adjustable along with the drive level. It's not quite the same with bipolars since the overdrive effects are more saturation than in the self-bias conditions of tubes. It's close, though.

From all indications of the Fourier series results, there's a definite reason why so few multipliers went beyond tripling. The amount of energy (relative to fundamental and taking into account the finite rise and fall times) of 4th and higher harmonics just isn't as much as intuition would have everyone believe!

No. Its the LACK of understanding of the Fourier Series which causes
blisters.

It is not surprising Fourier narrowly escaped the guiliotine. During that
era the French were ahead of the world in mathematics, statistics, physics,
etc. But the researchers were the idle rich of the nobility who did it as a
satisfying hobby.

For example, the idle rich used the technical subject of probability and
statistics to help themselves at the tables in the Parisian gaming houses.
This was not an activity likely to endear itself to the revolutionary mobs
behind the barracades in the streets of French cities. And so a number of
clever academics and noblemen fell to the embrace of Madamme Guilotine.
Napoleon soon put things on the right track.

Although Fourier Analysis was first applied to the conduction of heat by the
French philosophers it has, of course, since been applied to electrical
matters.

But it was Oliver Heaviside, a self-taught Englishman from the working
class, who many years later, around 1872 solved the mathematical problems
associated with the transient behaviour of electrical equipment and
transmission lines. He too ended up with an infinite series of terms, not
functions of frequency, but ot time.

The trace on the web site you provided a link to. The fact that you're using HC logic (which has inherent rise and fall times rather faster than the square wave source I used in my experiment). Your avering that the duty cycle is very nearly 50%. That's not to say you aren't doing something to kill it, but it's NOT difficult to extract it. Note that the subject you put on this thread really nails it: all you need to do is extract (and possibly amplify, depending on the final power level you need) what's already there. Now go do it. But feeding the whole square wave to the amplifier stage is a BAD idea because you can inadventently change the duty cycle (as seen at that amplifier's output) to one where the fifth is nulled. If you only need a few milliwatts, you can get that from the square wave directly, if the source impedance is low enough, simply by using the proper filter.

>rectify an AC signal and send it through a filter capacitor you STILL
>suggest to multiply it times 0.707.
>I would have thought that would give you the wrong result??

Uwe, Wouldn't be the first time I was wrong.
If you rectify and filter an AC waveform, and the read the DC voltage, this is Vpeak of the AC. In the example I gave, you read 2 vdc out of the detector circuit. Multiply this times the X10 divider, and you get 20vdc which is Vpeak across the 50 ohm load. To get the rms voltage across the load Vpeak*.707=20*.707=14.14 Vrms. 14.14Vrms across 50 ohms=4 watts.
BTW, the reason I suggested a voltage divider (attenuator) rather than reading directly with a VOM or scope is to reduce the likelyhood of the scope probe or meter impedance from detuning the AC-1 causing further errors.
If you are using a scope, measure the Vpeak across the 50 ohm resistor, multiply by .707 to get Vrms.

Ignoring most of the previous posts in this thread (sorry - I deleted them) it occurs to me that maybe the problem may be the relatively low impedance load on the buffer, whose finite output impedance therefore causes some waveform distortion and loss of 5th harmonic. So how about a hi-Z parallel tank coupling circuit; for 17.2MHz (say 4p7 || 18uH) into a load of 100-500 ohms (say a 1k pot + 100n to Gnd, to see the effect of load variations), then into another 74AC buffer?

Actually the tank's output will be biased to half-rail, which won't necessarily
bias the CMOS output buffer properly. May need to cap-couple to the buffer, with
a feedback resistor so it will self-bias (another case of reading the post AFTER
hitting "send").

They're great for LC filters. If you choose your ferrite right, you
can have a pretty stable filter over temperature. Problem is, not many
people make these any more. For production, avoid them due to
availability. If you're worried about inductance, that probably means
that you're in the MHz region which means you can use NPO (COG)
ceramic. Easier to get.

Don't laugh. Someone just today quite seriously suggested C0G bypass
caps for op amp power supplies for something I'm working on, and I'd
need at least 100nF for the task.

Cheers,
Tom

2210. Blowing NE602s.Why?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-18 06:10:14 UTC
From: n2cqr@clix.pt
Message-ID: <97f305da.0403172210.127a5942@posting.google.com>
Source record: 27598

I'm using an NE602 as a balanced modulator in a simple DSB transmitter.
The circuit is similar to that of the K2.
My problem is that in the course of debugging the TX, I've somehow
destroyed three NE602s. At first I thought it was voltage spikes
from the T/R relay, so I put a diode across the relay coil to knock that
down. Then I blew another one. Now I suspect that somehow the problem
is related to parasitics that I'm trying to eliminate in the PA: There is
an impednce transformer in the 602's output circuit that would look like
a big step up transformer to any RF that that nasty oscillating PA might
send back down to the modulator.

What do guys think? Is this a likely suspect? Anyone know of other causes
for this kind of 602 carnage? Stop me before I kill again!

Exactly how much power do you need? Exactly how "clean" (free from
other harmonics) must it be? Don't you have an amplifier in the
circuit you're playing with anyway? 100mW should be easy with a
single stage following the digital square wave, and a full watt is
certainly feasible with the right design. If you were hoping for
100mW of fifth harmonic from a single HC output, you were probably
dreaming.

Preferably filthy. It's another multiplier (this time only 3X, thank
God!)

>Don't you have an amplifier in the
>circuit you're playing with anyway?

Yeah, but who needs insertion loss on top of the 8dB the filter's down
even at centre pass frequency.

Egad, Paul! You've been wasting this much net bandwidth just to drive another HC gate?? All you need is a filter/matching circuit that steps up the voltage. This is DOG SIMPLE! See below.

> >Exactly how "clean" (free from
> >other harmonics) must it be?
>
> Preferably filthy. It's another multiplier (this time only 3X, thank
> God!)

Then you need a clean enough input that you'll get the desired output purity. "Filthy" is likely NOT the right answer and will just get you into further trouble. But fortunately, "clean" is simple, and "really clean" isn't at all difficult.

Try this: square wave output -- I don't recall your exact freq; I used 3.7MHz -- from HC gate, feeds 4.58pF capacitor (make at least that one tuneable). Other end of cap feeds 20uH inductor, Qu=200. Other end of that inductor connects to next gate input, and net 18.6pF of capacitance to ground: say 15pF cap plus 3.6pF of gate input capacitance. For DC bias, gate input to ground = 22kohms; gate input to Vcc = 47kohms. That keeps the gate in a valid logic state when there's no excitation. Assuming the gate's RF input resistance at 18MHz is at least 2.5kohms, you should get a voltage gain at the fifth harmonic of about 15dB, which will be ample to drive the gate input. The available current from the filter is low enough that the gate's input protection diodes should clamp things nicely at the rails. Be sure to use a gate that has input protection, or else add low-capacitance, fast diodes externally. Gain at the third and seventh is down 20dB or so from that. If it needs to be cleaner than that, you can add a second resonator.

The gate biasing suggested may result in an output duty cycle significantly different from 50%. If you will always have 3.7MHz drive, you can bias the input more in the center of its range, or even rearrange the circuit a bit and use a feedback resistor from output to input to set the DC bias. The gate's input impedance is then much lower, but you don't need much voltage to drive it. Don't use that

trick with a Schmitt trigger input, though.

69 turns of 36AWG (0.125mm) wire, spaced 2 wire diameters c-c, on an 0.375" former, should give you about 20uH at Qu=200 and first parallel SRF about 50MHz, but you should be able to make it more compact using something like a T-50-2 powdered iron core.

2216. How to trace a current fault.

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-18 18:18:23 UTC
From: Joe McElvenney <ximac@btinternet.com>
Message-ID: <VA.0000007e.003d7611@btinternet.com>
Source record: 27604

Hi,

I been beating my brains out for the last few days trying to run down a problem on a 20-year old Icom-740 transceiver with not a lot of luck. Perhaps someone here in the group has a trick or two up their sleeve to get me out of the hole I've been digging myself?

The situation is this -

The rig won't receive but transmits OK and there are no other fault indications.

The apparent cause is the regulator for the 8V receive line shutting down due to current overload (i.e. more than 100mA which is the limit of the MB3756). At present it is running at about 3.3V with around an 80mA load (lower than 100mA but the foldback circuit on the chip is operating).

All other supplies are normal; in fact the other two supplies out of the MB3756 are on the button and I have changed anyway it just in case. If I isolate the line and apply an external 8V the current goes to over 400mA in a manner that suggests there is a semiconductor junction or two in the fault path.

As these rigs are a mass of interconnections (the main board alone has 25 plugs/sockets on it), normal fault-finding procedure would be to monitor the current and yank the plugs one by one until the excess load disappears and then to have at it with a VOM. Unfortunately the system of on-board links that Icom use makes this a more difficult task than you would think. Over the last few days I've been sure I'd found the leak several times but was badly mistaken on each occasion. Of course, the fault may be an above ground supply line to supply line leak which wouldn't show up as an earth leakage path.

The tool I really need is a miniature Hall effect DC amp-clamp but there doesn't seem to be one available. In the past I've used a hp current tracer on PCB tracks but even if I had one now it wouldn't be easy to use here. However, I do have a bulky hp-1110A (2mV/mA) scope current probe and a 10526T pulser, so tomorrow I'll try that route with or without the power on.

Sorry about the windy posting friends but if anyone has any idea on ways to trace wayward current leaks, please let me know.

If the signal format is *exactly* identical to WWV it has a continuous
time signal being sent as a 100 Hz tone at 1 bps. If you can't hear
it on your radio (because of "comm grade" headphone or speaker or
ears), you can use skysweeper in free demo mode and see the bits clear
as day in the waterfall display.

Here is the WWV/WWVH time format:
http://www.boulder.nist.gov/timefreq/stations/wwvtimecode.htm

But as been mentioned before, this is a different format than what is
used by WWVB for synchronizing clocks.

Thanks, Tom. I'll give your suggestion a try. Just one question: is
the unloaded Q of 200 you specify critical? I probably have a 20uH
factory-made inductor laying about in my parts stash but won't know
it's Q without measuring it. Need I bother?

Not "identical." See -

http://www.boulder.nist.gov/timefreq/stations/lform.html#timea

The "tick" sounds the same from each station but is different in
the frequency inside the burst.

I had a similar problem with a shorted supply rail in an IC-746.

Since it was more accurately a *near* short, and the voltage regulator was pushing out quite a large current, there were actually several millivolts all along that rail. By using the DVM on its very lowest range, and taking the least significant digits seriously, it proved possible to trace the voltage gradient downward to the short.

The fault is worth mentioning too. It was one of those Icom ribbon jumpers, that I had inserted slightly off-centre in its slot. The surprising thing was that the transceiver had worked OK for about a month... but all that time, the ribbon had been creeping slowly sideways... until finally it had moved far enough to cause a short.

Hmmmmm.....don't know about the xfmr idea, but what supply voltage are you applying to the chip? I was faced with a similar situation once till I realized I was feeding it 12VDC when it's max rating is 9VDC.

Good luck.

You might be able to spot it by frosting each board with freeze spray then applying power to see what's getting hot. That won't work if the short's a really good one, and of course parts that normally dissipate a lot will show up too. But if it's a good short, a hot PCB trace might show up to reveal the location of the problem.

But that's not what I said. WWV has its own 1 bps digital signal,
every minute. If, as you say, WWVH has the same format, presumably it
also has the same 100 Hz digital format as WWV (no suffix).

BTW, I just built the suggested circuit, on one of those old white plug-boards which is NOT a great idea at RF. It worked fine. Easy to tune just with a scope. Performance was as I expected: full -0.6V to +5.6V or so swing at 18MHz at the input of the "18MHz" gate, and an 18MHz rectangular wave at its output. 74HC04 hex inverter; 3 stages as a simple RC oscillator to generate the 3.7MHz input. Duty cycle of that 3.7MHz was fairly close to 50%, but definitely not right on. The performance tells me that the 'HC04 really does have a fairly high input impedance at 18MHz, and requires under a milliwatt to drive--perhaps well under. There's AMPLE fifth harmonic power in that 3.7MHz square wave out of an 'HC04, and you just need to filter and do whatever impedance transformation is appropriate to get the desired result.

Incomplete filtering of the non-fifth harmonics causes variation in the output pulse width (in a cycle that repeats every cycle of the 3.7MHz input), and frankly if I wanted a pretty pure 15th harmonic at the final output, I'd use a bit better filter to get a cleaner fifth. But try the simple one first, to convince yourself that it's possible. It's a pretty "hack" circuit, in that I just made educated guesses at the 'HC04 input and output impedances at 18MHz, and at a reasonable load resistance for an 'HC04. It could probably be optimized a bit, but it DOES work as described.

Inductor Qu: The loaded Q of the circuit I described depends on the output impedance of an 'HC04 inverter, and the input impedance of the same with the bias resistors included. It should be running somewhere around 20-25, I believe. That determines how well the third and seventh are rejected. The unloaded Q of the inductor determines how much fifth-harmonic power is lost in the filter. You can stand some loss, but you don't want to waste too much. If the loaded Q is 25 and the inductor has an unloaded Q of 50, then you will waste half the power in the inductor. That probably would still work, but it would be better if the Q was more like 100, as a minimum. Based on what I've been hearing so far, I'm not very confident that you will be able to tell the Qu of your junque-box inductors, especially since you need to know it at the operating frequency. Qu of a lot of manufactured inductors is quite low, especially at non-optimal frequencies. If you picked a ~20uH inductor designed for use in a switching power supply at 100kHz, it could well be awful at 18MHz. It only takes a couple minutes to wind up an air-core one, so that's what I'd suggest. The one I used was 49 turns on a T-94-2 powdered iron core.

Cheers,
Tom

A common way to trace problems like this is to measure voltage drop
along the power supply traces and wires. They do have resistance, and
they do show an I*R voltage drop. You need a fairly sensitive meter
range to see the effect, but it's a very useful technique. Clip one
side of the meter to the regulator output, and start probing places
that it's supposed to go. Start with things connected close to the
regulator, and move out...when the voltage drop stops increasing,
you've passed the culprit.

Another way that's a bit more extreme is to connect another supply in
parallel, with current limit set to something that won't burn up PC
traces but will make the problem easier to find. Then you can trace
the current even by looking at (or feeling) temperature rise in the
traces! ;-) Or--look for the magic smoke escaping (but I suppose
something has already lost its magic smoke anyway).

Cheers,
Tom

Maybe you can wangle a couple of samples from the manufacturer.
http://www.highenergycorp.com/ceramic/ht50.html

This is supposed to be the replacement for the 850 series.

According to this page http://www.highenergycorp.com/ceramic/ceramic.html
they will sell in small quantities. It lists a toll-free number (for the
U.S., at least) and a link to a request form.

Ah! I too am a LowFER - Made a 6Hy coil in about 4 sq. inches on my
winding jig. No current capacity but a great 20-76KHz preselect for the
vacuum tube RX :-)

Reg is right, because those roller coils are particluarly popular on
the opposite side of the atlantic ocean. Those rollers are usually
only optimum on the lowest frequencies and efficiency decreases when
you use a smaller part of the coil

Another idea which not seems to be mentioned, but won't let you
measure down to nH, is to put an accurate 10ï¿½H coil in series with the
meter, and you should at least measure with reasonable accuracy down
to 1ï¿½H or lower. You may buy ready made coils down to below 100nH
which can be used to check the calibration.

My over 50 years old Radiometer multimeter uses this technique and
measures well down to 20nH. I made my own meter with 18MHz oscillator
to meassure 0.01-1uH

Hi Tom,
Thanks for taking the trouble to cobble together this circuit. I've done likewise here but am sorry to report that all I'm getting is the ubiquitous 3rd harmonic on 10.whatever Mhz as usual, regardless of what the variable cap's tuned to. I made the cap to ground variable as well, but no dice.:-(. The output looks as if it may well have some higher frequency content and could be filtered to recover a useable level of 5th., however. I don't think there's a quick and dirty way to achieve this - for you perhaps with your longer experience, but sadly not at this end. Looks like I'm going to just have to swallow hard and build some proper filtering and use a few more amplifying stages: no big deal but I just wish I'd known it from the outset as it would have saved me a lot of time and trouble. I don't think you can get away with short cuts at RF, especially if you're a non-expert.

Look for a shorted bypass Cap along the supply rail. These
small tantilum caps are notorious for shorting out, and giving
your symptoms. Just follow the rail on the schematic and isolate
each board one at a time untill you isolate which board is drawing
down the supply. Then look for the bypass caps on that board, for
any discolor or sign of excess heating.

I was told 40Mhz is "practically DC" too. I guess it depends on where
you're coming from.
Actually I've dumped the factory inductor as suggested by Tom and
wound-up a large, air core job on 15mm plastic water pipe. It's made
a big difference. I'm happy to report I've now got the 5th! Could be a
little cleaner but who cares? Tom made a big deal out of the
importance of high-Q so it was the obvious thing to try. Fortunately,
it's worked. God knows how I'm going to squeeze this monster coil onto
the board, though! :-|
Can I infer from this experience that SMD inductors of over a few uH
are a waste of time?

You're probably better off using stripline techniques, and for that you could scale a 1296 converter design. There aren't a lot of plans around for those anymore, either, because most people build a kit, and most of those are transverters. There may be an index of articles from back issues of Ham Radio. There are better active devices available than during the heyday of that magazine, but the design techniques haven't changed a lot. The picture at the bottom of this page http://www.ussc.com/~uarc/utah_atv/ka7oei_a.html shows an example stripline 1296 receive converter. As your antenna will be pointing skyward you may not need the bandpass filtering shown in the lower-right corner of the board.

You might find a used 1296 converter you could hack, or some help in building what you need, from the friendly hams at the Rochester VHF Group down the road from you. Down East Microwave (downeastmicrowave.com) has low-noise preamps for 1691, but no converters.

According to this site: http://daltron.com.pg/~nq/1691.htm, a good antenna and preamp will work with even a wideband communications receiver. That might be an easier route.

Source record: 27642

Hi again,

Thank you for your useful comments which were all duly noted. However I have been able to clear the problem after a deal of head-scratching. It became likely that the leak was between supply lines and not simply to ground when the PA cooling fan started-up on receive.

The fault turned out to be a s/c between the tops of two zero-ohm resistors (links) on the IF board just a little north-east of the speaker plug. As I was the last person to plug and unplug that particular lead, I guess that I must be the guilty party.

Thanks again - Joe

Ah ha! I have a 465 (w/DM44) that I purchased in 1978 for personal use
(no commercial abuse). Shortly after the warranty expired, it would not
power up.
I traced the problem to a shorted tantalum filter cap on the +15 volt
line.
But of course, it wasn't in the power supply, but rather on one of the
boards.
Pain to get to, IIRC.

BTW, I did not get option 5 (TV sync separator). I wonder if it is
feasable to
install it myself? Documentation is listed as 465 option 5 supplement

I think you can get adequate Q if you use a powdered iron toroid. I'm not going to take the time to look; there are some Q curves on the Amidon website. But I think that a T-37-2 core might work OK. I could also have a look at what's possible with a lower Q coil, but don't have the time right now. You could do that with Spice or with RFSim99, too. If you lower the "output" capacitor, you will raise the voltage delivered to the 18MHz gate input, given that the LC is resonant at the desired output freq.

A note on the effects of inadequate filtering... Of course, the result is harmonics other than just the fifth in the output. But what does that mean after you've squared things up by running the signal through another gate? How does a waveform which spends all its time at either 5V or 0V have multiple frequencies? It does it by having different high and low times on each cycle of the five output cycles that happen for each input cycle. And if you want a pretty pure 15th harmonic (3rd harmonic of the 5th harmonic), you are probably going to want the cycles to be uniform, and close to 50% duty cycle. (They WILL have plenty of third harmonic...the rise and fall times I observed yesterday on 'HC04s were about 4 nanoseconds, and that will get you up above 100MHz...) That will take more filtering. If your inductor Q is only moderate, you still have a chance if you build a higher order filter, instead of trying to do it with a single pole (really single pole pair) filter such as I suggested. You can do it with a single pole but it has to be quite high loaded Q, and the coil unloaded Q must be higher still. But you can make the multi-pole filter wider, maybe two or three MHz wide, and get by with lower Q inductors and still have reasonably low loss and adequate rejection of the other harmonics.

Yeah, the little moulded SMT inductors aren't very high Q. They are intended more for power supply filtering and choking, but you can use them in relatively wideband filters too.

Now that you've seen that it can be done, I hope you'll be inspired to see what you can do to make it better.

Cheers,
Tom

I wonder if we as a NG might put together a design
for an HF rig that could be built with ease by novices
and experienced constructors alike?

I suggest that none of the CB-style gadgets of today's
CB-style rigs are necessary and that a reproducible design
having only the facilities of, say, the KW2000, would provide the
basis of any station.

Keeping it simple will increase the chance of success.

I suggest the following....
DDS VFO
VFO display based upon graphic LCD to simulate
the use of a tuning knob-plus-dial.
Tuning knob plus flywheel using optical sensors,
giving the "Feel" associated with traditional rigs.

DSP for the audio and mixing stages, perhaps
with a low IF of ooo 50kHz to resolve the ringing
problems that arise in narrow baseband filters
for CW.

ooo 100mW output allowing the choice of PA
for CBers-Masquerading-As-Radio-Hams or
running barefoot QRP for _REAL_ Radio Hams.

Any of the established CB types in this NG are welcome to join
this discussion, I only ask that your contributions be
meaningful and not the inane sneering 'n; jeering for which
you are famous.

Indeed, and thanks, Tom. I shall be following up your concept in the
manner you describe; it's a departure from what I thought would be
suggested when I commenced this thread but it's the outright winner in
my book. There's a lot I don't know about coils - I never expected to
have to say that. But there's a lot more to them than meets the eye,

too so I don't feel too ashamed to admit it. Yes, it's a great
solution and the only drawback is the physical size of the inductors
which can be remedied with a little further development as you say.
That is what I plan to do next.
Thanks again!

Just a quick thought: how about changing the ratio of the C/L pair to
increase the C so a small coil can be made; keeping the resonant
frequency the same of course. Is there any inherent problem in trying
that approach (I'm sure there is or you would have already suggested
it).

Good but expensive, aren't they?
It would be great to see the people on this group design one here. It
would be invaluable info for those interested in furthering their
knowlege of the hobby and maybe the end product could equal or exceed
the Elecraft specs at a lower price?

I have no experience of the Elecraft kits, but I suspect
that the packing density of components on their PCB's
would mediate against future maintenance and fault-finding?

Also, for Britland, AIUI, there are problems for the man-in-the-street
having to organise his own shipping and passage through customs?

A kit of our own design would not be subject to proprietary
trade secrets. If the AF amp was specced at, say, 1mw into
600 Ohms, then almost any AF amp chip would do the job.

While on the subject of fault -finding, one RX which sticks in my
mind as being very easy to repair was the R210, because all the
aluminium chassis (pl?) folded out on hinges for easy access.

As part of being a _REAL_ Radio Ham is maintaining our own
gear, then there is food for thought in this area.

I think you better check out Elecraft -- befroe making pronouncements
of PCB compnent denisty. Active mail reflector with over 35 postings each
day.

> Also, for Britland, AIUI, there are problems for the man-in-the-street
> having to organise his own shipping and passage through customs?

Has been handled a number of ways for Brits, Germans and French.
The recent "cheap" US dollar rates to EU Euro and British Pound -
make the Elecraft offerings a bargain for Europeans.

> A kit of our own design would not be subject to proprietary

There are no trade secrets with Elecraft --
you can even download the K2 assembly manual.

> While on the subject of fault -finding, one RX which sticks in my

5,000 Elecraft K2 kits sold, built and supported -- speaks for itself.
Lyle Johnson designed a DSP option; a 60 meter board is completing testing
and VHF/UHF transverters were introduced earlier this year.

Paul,
If you are trying to keep things small, have you considered one of the high speed versions of the 4046 PLL/OSC? Some manufacturers spec these up to 20 MHz. No coils. If you go with the LC, and you have any fixed capacitors in parallel with the inductor, use decent capacitors, like mica or RF approved ceramic. I have seen cheap ceramic caps meant for bypassing just not work in applications like yours.

Are you trying to solder RG6? Easiest fix is to go buy a piece of RG59, if
you need 75 Ohm coax, or almost any 50 Ohm coax. I gather there is no wire
braid over the Al foil.

Fine radio the KW2000. Work great. One of my club guys has
nothing more recent in his shack for HF use.

> Keeping it simple will increase the chance of success.

Yup. Make it a similar project to the K1 and K2 Elecraft -
i.e. you can make it work in stages and use itself as a piece
of test gear too.

> ooo 100mW output allowing the choice of PA
> for CBers-Masquerading-As-Radio-Hams or

I feel this was a demonstration of the popularity and supporters
of Elecraft - not so to do with component density.

No, I don't think so. Have built a K2 #4030 about 8 weeks ago
with SSB balanced modulator and DSP options. It uses no SMDs
(except one case described below) and you can get at most things
for both DC measurements or for attaching a scope probe to.
On the DSP, there is a piggy-back board pre-manufactured with
the DSP chip as an SMD. Elecraft publish a DC voltage table
to assist in trouble shooting. The email reflector had plenty
of knowldeable Elecraft owners to assist or make suggesstions
and the Elecraft post-sales support is also good.

Also built a KX1 for a white stick op ham friend. If anything,
the component density on that and the add-on boards is higher
than the K2. It uses a couple of SMDs, the main one for the DDS.
But apart from that, most things are accessible. The KX1
was an ideal rig for my friend to take on holiday since it's
small and supports eyes-free operation with CW feedback.

A good idea.

There are a few people with the required knowledge.

Walt could help with the specification.

Gary (is it Peach) also.

Brian (G8OSN) is probably one of the few with the technical knowledge
needed.

You, Airy, could sweep the floor.

A good pair of designs where technical excellence took
precedence over traps-for-the-turnip-brained.

Now, it seems to me, that subject to the mixer performance
in the RX, that we could produce the functionality of the said
TX/RX pair, with the total circuitry occupying no more, say,
than an A4 sheet of paper if we were to use the modern
approaches of DSP and DDS.

What say you?

I have one of the small desk clocks that synchronizes to WWVB at
night. It auto-adjusts the internal crystal (or says it does)
to keep itself going during the day. I've found that it maintains
accuracy very well: certainly good enough for anything short of
atomic physics.

I live in the NorthEastern U.S., where the signal is relatively weak
(look at the maps at the URL a previous poster supplied) and don't
have any significant trouble with it. I looked at the NIST web
site, and I think they said something about boosting the power of
the WWVB signal: so if you had trouble with it before, it might
be worth trying again.

Yes, not to belabor the subjct, but WWVB is 60Khz,
while WWV, & WWVH are 2.5.....20Mhz.

There is no voice with WWVB. Howver, for calibration purposes
WWVB is more stable, and accurate.

No, the second ticks are 5 cycles of 1000 Hz on WWV and 6 cycles of
1200 Hz on WWVH.

You're right a wwv or wwvh clock both receive and decode
the same manner. Both wwv and wwvh transmit at 2.5, 5. 10, 15, & 20Mhz.
There is no 60Khz on Kiuai.

We were there at the same time. 69-87 for me.

I once had to put in a buried seismic alarm system right across the street
from that transmitter.
Took some interesting filtering on the signal lines, not to mention three
weeks to ditch through the coral.

That's a point well worth remembering, Tam: it's not just coils that
exhibit a Q-factor and just as much harm can be caused by using lossy
capactors in tuing applications, too.
The PLL suggestion is a good one, but I'm trying to keep things simple
for this fairly straightforward project. It's nice to be able to build
everything just from what's in the junkbox.

IMHO... QRP, for the new-to-HF ham whose Morse (and/or voice procedures) isn't all that solid yet... and who's probably using a comprimise antenna... is really not a good idea.

Save it for when one's got some experience under the belt & is interested in trying something new.

The homebrew design that would, IMHO, bring a lot of new folks to the HB fold, would be...

A simple, inexpensive, easy to duplicate, linear amplifier. 2-5 watts in, 50-100 watts out; good for all HF bands; run from 12V. (yes, there are certain advantages to using 28V, but 12V power supplies are cheap and ubiquitous. I know I misspelled that!)

It could be used with a wide variety of existing HB QRP transceivers, or with a variety of commercial QRP gear.

The alternative would be pretty silly though, wouldn't it? That is, the
more tests you pass the less power you are allowed. Nobody would upgrade,
would they?

2298. Low-loss toroids

Hi all,

I've been trawling through my various catalogues tonight looking for
toroids that might be suitable to wind hi-Q inductors around, but am
disappointed to see that all the stuff on offer seems to be geared
around interference suppression and is consequently - I assume - very
lossy material. Does anyone know of a source in the UK that can supply
small, *low-loss* toroids by the dozen to the hobbyist via mail order?

Thanks,

p.

Paul,

You need to look at powdered iron cores instead of ferrites.

Yes, powdered iron (I believe it's "iron dust" in the Queen's English) is what you want. The major manufacturer of suitable cores is Micrometals. Their products are sold by Amidon and others. Give their web site a look for general info, and a google search should yield some retail sources. For HF work, type 6 generally gives the highest Q, with type 2 in second place.

Quite so, Roy!

Micrometals website is - http://www.micrometals.com

The website has a nice, free, downloadable program for calculating
the number of turns for any of their toroidal cores for any of their
powder mixes for many sizes of magnet wire.

One of their publications is the venerable "Q Book" which graphs
the Q of many different inductances wound on their forms over
frequency from LF to UHF. If Paul can talk them out of a copy
he will find it indispensable for estimating toroidal inductors...
provided there is a supplier on his side of the pond.

Amidon is a reseller (Micrometals' minimum order is at least 100
of any type, or was). Most of the small quantities found in ham
and electronics stores here have some typical Q curves enclosed
in the plastic packet, curves originally from Micrometals.

Thats what i found out today. That its all RG6 locally ex. homedepto
radioshack. I can't seem to find any other sources (i'm at lehigh
university in PA in case anyone is close) I only need at most 2 feet of
this. Would anyone be able to ship me some if i were to cover shipping or
think of an alternative. I have a 2.4 ghz wireless network up right now
which i need to attach a home made antenna to. Aside from the antenna and
wireless transmitter all i have right now are f-connectors and a lot of rg6.
The antenna and card are still connectorless. I"m open to any solutions
some one may have. thanks in advance

2307. A weekly guide to Ham Radio

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-21 11:18:35 UTC
From: "Airy R. Bean" <airy.r.bean@lycos.co.uk>
Message-ID: <c3jtq9$27suha$3@ID-217727.news.uni-berlin.de>
Source record: 27594
Cross-posted to: uk.radio.amateur,rec.radio.amateur.homebrew

For those of you who have the necessary technical
motivation to understand how things work, have become
interested in Ham Radio but are confused by the
attitudes and activities of those who are really no
more than CBers-Masquerading-As-Radio-Hams,
I append a short article explaining the difference.....

What is Ham Radio?

Ham Radio is a technical pursuit for those who
are interested in the science of radio wave
propagation and who are also interested in the
way that their radios function. It has a long-standing
tradition of providing a source of engineers who
are born naturals.

Ham Radio awakens in its aficionados a whole-life
fascination with all things technical and gives
an all-abiding curiosity to improve one's scientific
knowledge. It's a great swimming pool, please dive in!

This excitement causes a wish to share the experience
with ones fellow man, and shows itself in the
gentlemanly traditions of Ham Radio.

Radio Hams are qualified to design, build and then
operate their own pieces of equipment. They do this
with gusto, and also repair and modify their own
equipment.

The excitement that drives a Radio Ham starts with
relatively simple technologies at first, perhaps making
his own Wimshurst machine and primary cells. Small pieces
of test equipment follow, possibly multimeters and signal
generators. Then comes receivers and transmitters. It is with
the latter that communication with like-minded technically
motivated people takes off. The scope for technical
development grows with the years
and now encompasses DSP and DDS. There is also a great deal
of excitement in the areas of computer programming to
be learnt and applied.

The technical excitement motivates Radio Hams to compete
with each other to determine who has designed and manufactured
the best-quality station. This competitiveness is found in DXing,

competitions and fox-hunts.

-----OOOOO----

However, beware! A Ham Radio licence is such a
desirable thing to have that there are large
numbers of people who wish to be thought of
as Radio Hams when, in fact, they are nothing
of the kind! Usually such people are a
variation of the CB Radio hobbyist; they buy their
radios off the shelf and send them back to be
repaired; they are not interested in technical discussion
and sneer at those who are; they have no idea how
their radios work inside and have no wish to find out;
they are free with rather silly personal insults;
they have not satisfied any technical qualification
and their licences prevent the use of
self-designed-and-built equipment.

These CB types engage in the competitive activities
with their Cheque-Book-purchased off-the-shelf radios
in a forlorn effort to prove that they are Radio Hams.

No _REAL_ Radio Hams are deceived by such people!

Perhaps she is stamping her tiny foot in a fit of pique?

Certainly she has shown her true colours in recent days,
if the quotes by "Super Sam" are anything to go by. Any pretence
that she may have had about never being uncivil have been
completely blown away, and she can be seen for what she really is,
and that is a bitter and twisted old harridan who is best ignored by
anyone who wishes to maintain standards in _REAL_ Ham radio.

Reduce the L to reduce the resistive loss - the essence of L
is the energy stored in its current carrying, and it is the current that
causes I^2 R losses. The energy stored in the C is static. (Yes, there
are some losses in polarising the dielectrics but these are small enough
to be ignored)

Source record: 27502

Airy,
What you said would be relevant only if you were trying to determine circuit losses due to "unloaded" Q of the components. I believe Paul is trying to determine the 'loaded" Q in order to obtain best selectivity (narrowest bandwidth). Is this true Paul?

In order to obtain maximum selectivity, the loaded Q needs to be as high as possible. In the case of a resonant 'tank', the tank reactances are loaded by the external environment. The circuit Q (or 'loaded' Q) in this case is Q=R/X. In order to maximize loaded Q, the X term (reactance) needs to be minimized. This means low L and high C.

In any case, the actual circuit losses will be a function of the ratio of unloaded Q (Q of the components) to loaded Q. The higher the unloaded Q of the components, the lower the losses in the circuit.

Joe
W3JDR

I offered help with your supposed attempt to design and build
a radio, to host some webpages, etc.

You have until 23:59 21/04/03 and then the offer is removed.

I presume you've ignored my email.

So much for me trying to promote gentlemanly behaviour.

Leigh....

(PS - discovered the eham.net site yet for technical
discussions Gareth?)

You had my offer of help both on this newsgroup and by email.

Offer still stands until 23:59 21/4/03.

Leigh....

How about you widen the circulation of this article to more
rec.radio.amateur groups Gareth.

Tell everyone where they are going wrong.

Or are you too chicken?

Leigh...

<snip destructive propaganda>

For someone who claims such a broad base of knowledge, your
viewpoint is pretty short-sighted.

The Amateur Radio SERVICE has something to offer EVERYone, and
those licensed under its regulations each have the potential to
contribute in ways unique to the individual licensee. Recognizing that
no two people will ever contribute in the same way, and that some will
never contribute more than their presence on the airwaves, is simply
part of the hobby.

There is truth to some of what you're saying, in terms of the
service producing many fine engineers and engineering techs, and of it
being home to those who love to tinker (I know, because that's a big
reason why I got into it). However, it is not required that all of
amateur radio's participants be fully qualified to "design, build, and
operate," as you state.

I suggest you take a good hard look at this link:

http://www.arrl.org/FandES/field/regulations/news/part97/

Pay particular attention to paragraphs a, c, and e.

Amateur radio's real enemy is not those who don't know an
oscilloscope probe from a soldering pencil. No, the real danger to
amateur radio comes from those, like you, who display nothing but
intolerance to newcomers who are interested in the hobby, but who may
never have picked up a multimeter in their lives.

So: Instead of responding to newcomers with elitism and arrogance,
try responding as an "Elmer." Inform them about the purposes behind the
service, and explain about the responsibilities that a license carries.
Also explain that the Amateur Radio service, like any other hobby, is a
mirror: The 'reward' one gets out is directly proportional to what one

puts into it.

Remember: People learn by example.

Mr. Bean (no disrespect intended),

Well done. Couldn't have said it better myself.

Anecdotaly (sp ?) those very thoughts came to me a couple years
ago when a local Extra class operator (here in the colonies) was
on the two meter repeater desperately looking for someone to
repair his malfunctioning 12 volt DC power supply for him.

His highest-class-license meant nothing. Seems he had memorized
enough to pass his test and had no technical ability at all.
My thoughts at the time were that he was about 9 meters short
of where he belonged.

I know this thread will have a much longer life than it should
and it is close to being off topic (if not entirely), but I
couldn't resist agreeing with you.

No. It is not short-sighted. Ham Radio is a technical
pursuit with technical privileges and I wish it to remain so.
Any sitting-on-the-sidelines while the Mongolian hordes
of turnip-brained CBers pour in is ill-advised because the
powers-that-be will come to perceive Ham Radio to have
become indistinguishable from CB Radio and the technical
privileges will be in danger of being withdrawn.

Far from being short-sighted, the viewpoint that I
express is long-sighted.

I disagree with you there. To welcome and to encourage
newcomers who have already demonstrated their future relevance
by being technically motivated is one thing, but to
swell the ranks, just for the sake of swelling, with those
who are CBers, and who will always remain CBers, and
will never be more than CBers-Masquerading-As-Radio-Hams
is quite another.

BTW, It is CB Radio that is a "hobby". Ham Radio is a technical
pursuit.

I don't agree that it is OT. The manufacture of one's
own equipment, "homebrew" is the essence of _REAL_
Ham Radio, and that was reflected in my article.

Krem-

Is it possible to twist some of the shield into a sort of wire? If so, you might be able to crimp it to a terminal that can then be soldered. I would think almost any kind of crimp terminal would do. You could use a pair of side-cutting pliers to clip off the excess material from the terminal.

If not, give Radio Shack another chance.

Some clarification is necessary!
The application is the tank in a frequency multiplier.
I am seeking to select for the 5th harmonic. Therefore, the tank needs
to have as little loss as possible given the fact that the 5th will be
way down dB-wise on the fundamental. I can't afford to attenuate it
too much as it's already weak to begin with. Ergo, I need the lowest
loss components and the best selectivity for the desired 5th harmonic.
Thanks,

p.

Mr.Turner's outburst below says, perhaps, more about his own
psyche than he intended to reveal?

There is no "self-centred, holier-than-thou" proclamation
that I am "vastly superior" ..... "to the unwashed masses" in what
I assert.

In my book, _ALL_ comers of whatever race, colour, creed,
occupation, previous pursuits, are welcome to join the technical
pursuit that is Ham Radio, and in so doing, to tackle and pass the
examinations that are set to guarantee technical competence.

Those that demonstrate their technical motivation and competence
are welcome as Radio Hams. Those that lack either attribute are
not Radio hams by any stretch of the imagination.

The mobile phone and the CB transceiver cater for such non-Hams.

Source record: 27519

Circuit Q = omega*L/R. Reducing L has little or no effect on Q because, after winding L, you will find R has decreased in about the same proportion. The fewer the number of turns, the shorter the length of wire, and the lower the resistance.

The ratio of L to C also has little effect on circuit Q because the intrinsic Q of capacitors is usually an order of magnitude or more greater than Q of L. L and C values of a tuned circuit are usually selected by the reactances required of them at resonance for reasons independent of circuit Q. Eg., the reactance of L and C may be required to be 300 ohms at resonance because other components will have to be connected to them.

Usually it is the value of C which controls the value of L. C may have to be trimmer. If it is a fixed value it will have to conform to a preferred series of values and tolerances. If it is too small it will get lost in stray and other circuit capacitances.

IMPORTANT - Intrinsic Q of a solenoid is directly proportional only to its physical size. Double all dimensions, including wire diameter, and Q is doubled. Its the the amount of space you have which decides the value of Q. And there's a similar relationship even for magnetic cored components. If you havn't got the room then you will have to put up with a low coil Q. And it's always lower than what you think it is. Its impossible to measure in situ. Spice is of no help.

Don't forget that a tuned circuit is never used in isolation. If it is used as a filter in transistor collector circuit then it forms only part of the transistor load. And whatever else is connected will reduce the effective circuit Q. It could be that it doesn't matter what the intrinsic Q of the coil may be provided it is not ridiculously low. Which I suspect to be true in your case. You may be doing your nut about nothing.

To put it crudely, it is seldom that coil Q matters. Nearly always whatever you've got is good enough. If in a particular application you might think it does then you are barking up the wrong tree.

Absolutely not!!!!!!!!!!!!!!!!!
He needs best possible loaded Q for maximum selectivity! Good unloaded Q
will help minimuze circuit losses, but won't help with selectivity.

I don't agree. The selection of a harmonic is a
signal processing function and not one of power transfer.

Paul, in approaching the problem from your viewpoint havn't you set yourself the task of winding an inductor to have a particular value of Q ?

If you intend to use a solenoid then Q can be increased only by increasing its physical size without changing its proportions too much.

Utimately you will need to know what is the Q of a particular size coil, number of turns, wire gauge, etc. It will be reduced by its proximity to other components and circuit board by some indeterminate amount. I think you should stop and check whether you have room for the coil in the equipment space available. ;o)

Program SOLNOID2 may be of assistance in this onerous task.

Download in a few seconds from website below and run immediately.

ANY part used to perform a function which it is not suited for is a
waste of time. It would be interesting to know which SMD inductors you used
that seemed to eat up the 40 MHz so effectively. I'd be willing to bet that a
quick look at the spec sheet would show why that particular part was a bad
choice for that particular job.

Loaded Q or unloaded Q? If the load is in parallel with the tank and a fixed value, decrease the reactance of the tank elements. If the fixed resistive load is in series with the L and C, increase the reactance of the tank elements. Generally you should design the Q to fit the task. (You could expand on that: generally you should design the circuit to fit the task...)

Unloaded Q is increased by things like using the right core material and right winding techniques. There's not a simple answer. For air-core coils, the larger the coil the higher the Q possible, up to the point where radiation becomes significant. You might hear that helical resonators are very high Q, but actually the same coil in freespace will be higher Q, so long as it's not so large it radiates a lot. Reg has a program that estimates unloaded Q of air-core RF coils.

It's a fairly complex subject...don't expect one answer to fit all situations.

Cheers,
Tom

"The selection of a harmonic is a signal processing function and not one of power transfer."

Exactly Airy.
The output of the multiplier stage, which contains many frequencies, needs to be processed in order to select the desired component and reject all others to the best extent possible. This is an indirect way of saying you need a very selective tuned circuit.

The selectivity of the tuned circuit is defined by it's loaded Q; ie, the Q of the reactances in network loaded when by their operating environment. This means that for best selectivity, the reactances of the L and C should be as low as possible, which in turn means that the C should be as large as can be achieved, consistent with realizably small L and component (unloaded) Q. Unfortunately, as the ratio of unloaded component Q to loaded circuit Q gets small, the losses go up. This implies that there's a tradeoff to be made between selectivity and loss. Thus it is in the world of real components - in the world of DSP things can be different.

If you want high selectivity, you have to balance it against tolerable circuit losses, at least with real components.

I can imagine. Tantalum caps are a real pain in the ass. If you
reverse the polarity, they burn right through the PCB after a few
months! We got a board in for repair last week with that problem.
Luckily, everything on the board (yes, even the stickers with the
serial numbers) is self extinguising.

Be that as it may, Reg, how satisfied are you that your program
accurately calculates Q in the inductors in which it predicts
characteristics? For example, it is accepted by all (I hope) that
Q(unloaded) is at a maxium when the length of a coil equals its
diameter. Your program doesn't seem to reflect this fact. How come?

Let me clarify. Because Q is largely out of your control, the logical way of circuit design is FIRST OF ALL to allocate a practical, reasonably attainable value of Q to the inductor, taking the SPACE AVAILABLE into account.

Then design the remainder of the circuit around it to meet the required objectives. You really have no alternative.

Choosing a starting value for Q without knowing the inductance depends entirely on experience and visual imagination. But you will find program SOLNOID2 very useful in getting you in the right ballpark - only after you decide on the space and clearance available for a coil.

I'm still toying with the idea of using an oscillator locked to the 5th harmonic. Q and size of the coil don't matter two hoots. And you have all the output you could possibly want.

On second thoughts I would probably have gone about the whole job in an entirely different manner. ;o)

>Thanks,

Design of that is a two-step process. First, you need to establish
the impedance (or admittance) of both source and load. For a
parallel-resonant circuit selectivity device, they are both in parallel
with the unloaded Q of the resonant circuit. For a series-resonant
selectivity device, they are in series with it.

With vacuum tube and FET circuits, staying in the linear I/O bias
region, the first step is easy. Just parallel drain or plate resistance
and a gate or grid circuit resistance for a parallel-resonant circuit.
With bipolar transistors, the base resistance is quite low compared
to tube (valve) and gate inputs, must be impedance-magnitude
adjusted such as with tapping down on an inductor. There are
several other ways to do impedance-magnitude adjustment; that
coil tap is a very common one.

Once into a non-linear operation region the overall impedances
become dynamic rather than static and depend on drive level and
the amount of time an input spends in non-linear region versus the
linear region. Using digital logic devices means that the non-linear
regions are above saturation and below cutoff but the saturation
does not behave the same as with valve grid current run positive
on part of the cycle. That is NOT easy to calculate and quite
complex for those who take the time to do that.

For home workshop design efforts in getting to the task in the
most expeditious way, simply Cut And Try. Reg Edwards

pointed that out semi-directly. :-)

The second step is to select and inductor with, for your needs in being selective to that elusive 5th harmonic, of the highest Q_u (unloaded or "not in-circuit" quality factor) that will fit in the space (physical space) you've alloted. That selection is a compromise in size - cylindrical or "solenoid" cores mean (as Reg said) the bigger the better. I'll also add "the bigger the wire diameter, the higher the Q" for the same coil former size. For iron powder toroid forms, the powder mix is important as well as the size as well as the wire size.

Just from memory of a few years ago, a Micrometals T37-6 core (the "37" meaning 0.37 or 3/8ths inch, powder mix 6) will yield a Q_u of 80 minimum at 18 MHz using the largest wire that will fit through the center hole. Q_u at 17 MHz will be very close to that.

Unloaded Q is a result of many factors and all of those can be modified by things such as the dielectric material of a solenoidal former and the presence of adjacent shielding and even dielectric material. For the easiest application and less time worrying nit-picky details, pick an iron powder core toroidal form...such can be smaller than cylindrical formers allow and are much more forgiving of adjacent/nearby objects. But only if space is at a premium. Small toroidal forms can be difficult to wind for some and multi-turn inductors need lots of wire which can build up in the center hole, precluding use of larger magnet wire diameters.

Part of the second step is to combine what you know (or guess) in the first step with a selection of inductance and capacitance for resonance. As others have said, inductive Q_u is the determining factor at HF and capacitive Q_u will be at least 10 times higher, probably in the neighborhood of 500 to 1000 for ceramic or mica capacitors. Do a quick model of the resonant circuit "resistance" (actually the magnitude of impedance) at parallel resonance - parallel the (inductive Q_u times inductive reactance) and the (capacitive Q_u times the same reactance since capacitive reactance is equal to inductive reactance at resonance). Parallel that with the source and load impedance magnitude combined magnitude and you have the total magnitude at resonance. This can be very quick to do with a scientific pocket calculator.

To verify the selectivity, run the whole thing again at adjacent harmonics to get the total magnitude of impedance there. Those off-resonance L-C circuit magnitudes can use just the reactance as an approximate step and be very close to those using the unloaded L-C Qs. The ratio of magnitudes on-resonance versus off-resonance will give you a picture of the selectivity possible.

If that "doesn't seem to be good," THEN pick a different L:C ratio and do it again...but use what you know about the inductive

Q_u at that different inductance. Compare the new on-resonance
impedance magnitude to the adjacent off-resonance magnitudes.
Is that magnitude ratio worse than before? If so use an opposite
L:C ratio. If better, try the same-direction different L:C ratio and
compare that. If better, repeat. If worse, hold on the previous
L-C combination...you are zeroing-in on what is useful.

SELECTIVITY is the thing desired in your application and the
relatively-simple calculation of magnitudes and resulting ratios
will point in the right direction for something to try in hardware.
Selectivity is needed because the lower harmonics have more
energy than the 5th.

If stumped for a starting L and C value, try the literature on
previous multiplier designs as a starting point...then dance
through this two-step procedure.

In practical hardware, many others besides myself have been
led astray by simplistic "L:C ratio Q determination rules" that
can be just the reverse. Lots of those old maxims were
generated way back in time of large "coils and condensers"
one needed both hands to pick up...

Paul,

I probably should have included more details. A fellow I was working with was trying to extract a clock signal from a synchronous data stream, and was getting nowhere. We swept the frequency back and forth to be sure he was tuned to resonance - he was. Changed the ceramic cap to mica, and everything worked like a charm. We never analyzed why the ceramic did not work, but I suspect it was because of the capacitance vs. applied voltage dependence. If the cap had 6VDC on it, and he had a few mv of RF, I expect it would have worked. Instead, he had 0 bias, and a couple of Volts p-p signal.

BTW, somebody mentioned powdered iron toroids. Sounds like a good idea.

Hi,
Anyone know of a good place in the USA to buy TOKO inductors? I am looking
for these Part numbers:
BKANK3333R,3334R,3335R
Thanks Tom

DigiKey carries some Toko inductors but they don't list yours. The Toko
America site has no search engine. The way those part numbers are formatted
is BKAN K333R, etc, I believe. What was their original intended use (CB
radio, TV)? That may guide you to a source.

I'm sure I could send you several feet of RG-59 if all you need is
some 75 Ohm coax with copper braid. If you need a different impedance
I can probably come up with just about anything else that's common.

OTOH, I'm not familiar with RG-6. Is this the stuff the cable TV folks
use? Is it a braid or foil shield? If it's foil, there's usually a
copper shield drain wire that you can solder to.

Email me with your address and what you need if you need some
different coax.

> No. It is not short-sighted. Ham Radio is a technical
> pursuit with technical privileges and I wish it to remain so.

Well, that's fine. You can, in your own way, make your
participation in amateur radio as technical as you want.

HOWEVER -- Technical pursuits are NOT the only reason the SERVICE
exists. You apparently did not take my advice to read the material at
the links I provided on Part 97 of the FCC regs, more specifically the
section which defines what the amateur service is. Had you done so, you
would have read that there's a lot more than the technical side
involved.

> Any sitting-on-the-sidelines while the Mongolian hordes
> of turnip-brained CBers pour in is ill-advised because the
> powers-that-be will come to perceive Ham Radio to have
> become indistinguishable from CB Radio and the technical
> privileges will be in danger of being withdrawn.

<blink>

You know, up until you made that utterly inaccurate and utterly
loony statement, I was under the impression that you could be
reasonable.

> Far from being short-sighted, the viewpoint that I
> express is long-sighted.

You are, of course, entitled to your opinion. I would, however,
point out that the "Mongolian hordes" (are we being racist now as well?)
have been "pouring in" for the last several decades.

While there has been a noticeable (and, IMO, lamentable) decline
in the number of tinkerers, as it were, amateur radio is still around,
and I think it will continue to be around for many moons to come.

For the sake of avoiding newsgroup clutter, I will no longer
debate these points with you. It is apparent that you do not care enough
to take Part 97 (or whatever its UK equivalent is) seriously.

God help whatever newcomer asks you an 'elmer' type question about
amateur radio...

PLONK!

> Anyone have this info?

Yes, you can install it youself. The OPt.5 is a small extra board,
basically a video clamp circuit. There is a small ek special IC on the
board, but when you analyze the circuit you will recognize that a quad
op-amp of gain-BW > 5 MHz will work well.
At least at mine it does so.

Scopes with option 5 have a differnt front panel layout. So, you might
get in trouble to realize this with your non-opt5 scope.
But basically: Yes, it can be field installed.

hth,
Andreas

For years Amidon was pretty much the only place hams bought ferrite and powdered iron cores. A different company sprang up a few years back, composed of some former Amidon associates as well as former Amidon employees, and they are selling the same things. (Their reasons for going out on their own involves, I believe, discontent with their relationships with their former company, something which is hardly uncommon in the business world.)

The name is Bytemark, or more properly CWS Bytemark, since it merged with CWS a while back.

The URL is http://www.bytemark.com/ and the site has a lot of technical info on the toroids.

At least one of them is a ham, Tracy Markham, N4LGH, who was the driving force behind the original Bytemark. He's a homebrewer and was active on the QRP mail reflector for a few years.

I spent the morning parusing google groups, and found many different answers for the same question.

What I'm trying to understand is; on a disk capacitor that is labeled 560, common sense would tell me 56pf instead of 560pf since 561 on a cap would be 560pf.

Many have asked, but no one ever gave a definate answer. Can anyone give me a definate answer on this?

Thanks for the assistance

Yes, ceramics are *hopeless* for tuned circuits; I wouldn't trust the
black tipped ones, either. You can't beat silver mica but they're a
bit hard to find and expensive.

>BTW, somebody mentioned powdered iron toroids. Sounds like a good idea.

Indeed. I'm looking into it.

I have capacitors marked "330" that are 33pF, and capacitors marked "330"
that are 330pF. If it's xx1, xx2, etc., then you can trust it, but if it's
xx0 and you don't know that manufacturer's numbering scheme then you should
measure it!

I wonder what was Mr.Reay's purpose in publishing
his rather silly and somewhat infantile attention
seeking outburst that is quoted from him below?

Was it to demonstrate that not only is he a _LOSER_,
but that he is well aware of the fact?

Was it to demonstrate that anybody who holds, or who
has ever held, an M3/CB Fools' Licence can never be
a _REAL_ Radio Ham because of the associated
gentlemanly traditions?

Was it to demonstrate the really big mistake that was made
when the gangrenous degeneration that is the M3/CB Fools'
Licence was introduced?

Was it a further Freudian Slip on his part showing that
the insecurity that he holds to be in every _REAL_ Radio
Ham is a part of every fibre of his being and that he is
trying to make himself feel better by blurting out some
playground-style insults?

Was it to demonstrate that his sneering 'n' jeering in
the company and style of so many of the toilet-mouthed
gutter-denizens of this NG makes him a CBer fair and square?

Was it to divert attention away from a style of debate that
can at best be described as, spin-doctoring, side-stepping,
bullshitting and downright lying?

Was it to demonstrate that the RSCB, of whose politbureaux
he is a significant member, has degenerated into a
cesspit of CBers and is no longer relevant to Ham Radio?

Was it to make a fool of himself in front of Victoria,
Rebecca and Michaela when the time comes that he is no longer
able to censor their Usenet access, and they get to see
what a hypocrite he is by comparing his behaviour against
the standards that he imposes on them as they grow up?

Was it to demonstrate that despite his _BOASTS_ of being in
possession of a number of degrees that he is incapable of
stringing two or more words together in a civil and rational
discussion?

Was it to demonstrate that once again, having sneered 'n'
jeered in the CB fashion he is going to run away when
challenged?

Was it because he was annoyed that his gaffe in stating
that e^(-jwt) was a function that decreased with increasing time
was so well publicised, and he wanted to stamp his tiny little
foot in a pique of anger?

.....which goes against the true spirit that has taken
amateur radio to it's present position.

If the pioneers in the 1920s who did the first amateur
transmissions had adopted the same opinions and stand-points
as Gareth, we'd have got nowhere.

Long may he sit and rule his own empire. Thankfully that
empire ends at his front door except for his publicity machine
that is the internet.

It's sad but true that some manufacturers use "560" to indicate 56pF
and some use "560" to indicate 560pF. I've fretted over this same
thing in the past. I have examples of both. Fortunately, the trend
seems to be toward the usage that, as you say, is common sense. Too
bad it has not been universal.

Cheers,
Tom

If you are ever lucky enough to meet Dr Reay then you will learn why he posts the odd jibe at you. While you are directing your bile at him it goes into his kill file and he ignores you knowing that newcomers will see you as the nasty bit of work your are. That means the M3 are left alone and you do less harm. Brian isn't the sort of man to be worried by a toe rag like you.

More power to your elbow Brian

>Phew! Thanks, Len. There's rather more to these ''simple inductors"
>than meets the eye, it seems. :(

Yes, but it probably took longer to write the procedure out than
to actually do it. :-)

As a _starting_ procedure, work with magnitudes of impedance,
or the square-root of the sums of the squares of resistance and
reactance. That's easy enough on a conventional "four-function"
pocket calculator that has the added square-root function.

For a single resonant circuit you should be interested in the ratio
of magnitude at desired frequency to the magnitudes at the
undesired frequency. The bigger the ratio, the better selectivity.

If you want to investigate toroidal coils (for their smaller size), you
can find Q curves at - http://www.amidoncorp.com. Those look
exactly like the Q curves in my Micrometals Q Curve subsection
of their (surface mail only) catalog. Under one of the links at the
top right you will get a rather long html page with over a dozen
curves on it representing over a half dozen typical inductors per
graph over a wide frequency range. Save that page if you can,
it is good for reference later.

www.micrometals.com seems to be down on Monday, probably
for website revision; haven't heard any rumors that Micrometals
went out of business. Micrometals has foreign (to the USA)
distributors and sales reps so I was hoping to show some of
those in or near the UK.

For cylindrical coil shapes, Reg Edwards program is about as
good as it gets to save wear and tear on pencil and paper.

>QRP mail reflector for a few years.

Amidon Associates started up in Burbank, CA, in 1963 as a small
business by Bill Amidon, then with NBC at the NBC western Hq
complex in Burbank. The product was small-quantity reselling of
Micrometals powdered-iron and Fair-Rite ferrite products, packed
one to a few in small plastic bags found on display racks in hobby
electronics stores.

Micrometals was begun in 1951 in Orange County (just south of
Los Angeles County that includes Burbank). Micrometals is a
powdered-iron product manufacturer who sells in large minimum
quantities. Micrometals is also the origin of the Q curves (found in
limited quantity in Amidon packets) and the part number format that
so many now associate with Amidon. Micrometals doesn't sell
directly to hobbyists (unless they order a minimum quantity) but
Amidon Associates did/does. Amidon reselling was and is a good
service for hobbyists.

It is my understanding (but no proof) that Bill Amidon was a ham.
His name doesn't appear on a QRZ search. For a part-time
business started 40 years ago, Amidon Associates changed
addresses a couple times and seems to have been purchased by
another group and turned into "Amidon Corporation." That company
has a website at http://www.amidoncorp.com and you can find
many, many Q curves (good for reference) on one of their inernal

pages plus a lot of data good for planning powdered-iron toroid or ferrite applications. Amidon Corporation is headquartered in Costa Mesa, CA, and claims it has "manufacturing" (probably like a lot of distributors claim pseudo-ownership of the companies on their product card). They will sell small quantities of forms, wire, 3M tapes, teflon tubing, the older Amidon Associated kits, etc., and have an 800 number listed "for hams."

Yes, CWS Bytemark exists also, headquartered in Santa Ana, CA. [all the powdered-iron companies have gravitated to Orange County? :-)] Under the "Parent Company" there, it comes out that Coil Winding Specialists owns them and deals or resells a number of frequency products, some of them from Asian manufacturing locations.

I'm not going to delve into "business practices." Such doesn't have any bearing on "Low Loss Toroids." I do know that Amidon Associates had a very handy and useful service for hobbyists (myself included) in reselling Micrometals products. I do know that Micrometals has a quality product after specifying orders from them at work. The original Micrometals toroidal form ID format has now assumed a "Texas Instrument" kind of status in that many others use their same nomenclature...like "7400" is a quad 2-input NAND logic IC package identifier to all regardless of who actually made it. :-)

I could mail you some, but there's bound to be someone closer that
could get it to you faster.

Another option: crimp on an "F" connector and solder an F socket to
the board (perhaps with short wire leads, if the frequency isn't too
high).

You can also get solder that works on aluminum, but that might well
take longer than getting coax with copper braid. BTW, I have Teflon
RG-6-type that has solderable braid (plus foil).

Cheers,
Tom

I strongly disagree with this. I've successfully used ceramic capacitors many times for both high and low Q tuned circuits from HF to UHF. Years ago, I found that NPO ceramics were decidedly superior to silver micas for temperature stability, so I use them exclusively for VFO tank circuits.

You might have come across some bad parts. Or perhaps you don't realize that many different types of ceramic are used for making capacitors. Three general classes are most common. The "general purpose" class (something of a misnomer) is a very high-k ceramic used for capacitors of Z5U, Y5V and similar types. Those are very good for bypassing because of their small physical size, but terrible for nearly anything else. They're microphonic, hygroscopic, piezoelectric, and highly temperature and voltage dependent.

Another class is used for X7R and related types, sometimes called "stable". These are much more stable in all respects, but are physically larger due to the lower dielectric constant (k) of the ceramic. They're suitable for a wider variety of uses, but still not for high Q tuned circuits. They should be used in low Q circuits only after evaluating the potential effects of temperature and voltage dependence, at the least.

The third common class is used for making capacitors with near-zero temperature coefficients, such as C0G (formerly and still often called NPO). These *are* an excellent choice for tuned circuit applications, and are often better than silver mica (whose temperature coefficient and Q are variable and unpredictable). They're sometimes identified with a black dot -- on "dog bone" capacitors, it's on one end.

Many years ago I published an article describing a stable, VFO controlled QRP transceiver which used NPO ceramic capacitors for the oscillator tank. Scattered feedback indicated that some people had gotten "NPO" capacitors from less-than-reliable vendors and were experiencing an objectionable amount of frequency drift. That didn't happen with name-brand parts. So there are some flakey capacitors out there. If you need to depend on the quality, get name brand parts from a reputable vendor. And you'll find that NPO ceramics are a very good choice for tuned circuits.

Me, too. I solved the problem some time ago by picking up a really cheap DMM that measures capacitance as an extra feature. I'm sure it's not super precise, but it can easily tell the difference between 56 and 560 pF. My capacitors are sorted by decade in plastic drawers. Questionable ones get checked before going into (or back into) the drawer, so from then on I can tell which it is by which drawer it's in.

Roy,

We were talking about bypass type ceramics. See the 3/20 10:13AM posting.
BTW, I think with SM you are pretty much forced into using ceramics.

Of course, maybe you don't need such a high Q, Paul. Qu of 30 is
quite reasonable for small SMT RF inductors, at least the type I use.
In the following list, "series" means in series from the gate output
to the next gate input, in order, and "shunt" means shunt to ground at
that point. Anyway, try this (build it or SPICE it or RFSim99
it...add resistors to any simulation to account for the Qu. I'd
suggest 3 ohms series and 12k ohms shunt for each 1.8uH.)

47pF series
1.8uH series
470pF shunt
45pF series
1.8uH shunt
3.3pF series
40pF shunt
1.8uH shunt
DC blocking cap series
high-value DC bias resistors, and the gate input (I assumed to be
about 4k net resistance to ground at the gate input, including the
bias resistors).

It should give you enough voltage gain at 18MHz to drive the second
gate at the fifth harmonic, and should attenuate the third at least
50dB if you build it properly, even with low-ish Qu inductors. This
is rather a "hack" circuit, but works. The premise is that it's
easier to get three inductors all the same value than muck about
tuning the inductors. Make the 47pF, 45pF and 40pF caps variable and
you can peak up the response at your desired frequency. Your
simulation should show a reasonably flat bandpass characteristic,
centered at about 18MHz.

Perhaps you were talking about bypass type ceramics, but the posting I responded to:

>
> Yes, ceramics are *hopeless* for tuned circuits; I wouldn't trust the
> black tipped ones, either. You can't beat silver mica but they're a
> bit hard to find and expensive.

made no such qualification, and even specifically mentioned "black tipped" (usually NPO) capacitors.

As far as I know, silver micas are getting pretty rare, except maybe for very high power, high current RF applications, if they're being used for even that any more. I doubt if they exist as surface mount parts. The reason silver micas are hard to find and expensive is that they've been made obsolete for nearly all applications by generally superior ceramic types.

I note that the "Q" of capacitors when specified is much higher than the
specified value for Ls.
Unloaded Q will give maximum selectivity but no power transfer.
Optimum power transfer will be at q/2 which will only increase bandwidth
x 2, (i think but am not)

If its RG6 then it does have a continuity wire, you have probably
nicked it off in stripping back the outer sheath. The best given so
far suggestion is to use a twist on "F" connecctor - unless you can
borrow the proper crimping tool for crimp connectors. BTW, cable
losses at 2.4GHz will be astronomical, virtually nothing will be
getting up to the antenna. - or is it 2 feet from the card, then
acceptable. Even so, RG6 has the only virtue of being cheap, with
highly variable quality. have a talk to the engineering department at
school (if there is one) or do a internet search for a local 802.11
group near you, they are usually glad to assist in these cases. If you
have lots of money, get a USB wireless card and put it on the back of
the antenna, you can then run heaps of cable out and so get it to a
high spot.

My favorite meter is the LC Meter IIB sold by AADE as a kit.

Does a good job measuring Capacitance and Inductance...the L meter is REAL handy when you're tearing apart VCR's and old TV's for parts scrounging!

http://www.aade.com

It's a hand-held, digital

Inductor inductance meter
Capacitor capacitance meter
with a four digit display,
a maximum resolution of 1 nHy / .01 pF
a maximum range of 150 mHy / 1.5 uF.
The unit features
AUTOMATIC RANGING and SELF-CALIBRATION.
"It is a solder it together and it works kit."

I agree with everyone else James...

having said that, I don't have a C meter myself and I use a lot of components recycled from old boards, and I've never yet had a problem. In fact I've never even thought about it, I just rely on intuition. Seems to work Ok. I suspect there are a number of subconscious variables that go into this, like the nature and function of the circuit it came from, and probably most important, what does the capacitor look like! How big is it, what shape is it (how fat etc)., and how this compares to some other capacitors found of supposedly similar value which are unambiguously marked.

Cornell Dubilier / Waldom makes surace mount siler mico caps. You can
get them from Digikey for under $10 US.

You can get standard PPS film capacitors from several makers. If you
don't mind the fact that they are very touchy and have a higher failure
rate they may be an option. If you want a little better, you can buy the
more costly coated ones.

I wouldn't say that you are forced into using ceramic. It is an option
you may perfer.

The CDE "MC" series of cazapitors are "mica", not "silver mica". The
difference is that silver mica caps have to be sealed (dipped) or the
silver plating reacts with everything. I'm not sure what plating is
used for the "MC" series of surface mount mica. My guess(tm) is
aluminum.
http://www.cornell-dubilier.com/mica/mica.htm
http://www.cornell-dubilier.com/film/hmc.htm
http://www.cornell-dubilier.com/catalogs/MC.pdf

The big advantages of silver mica is stability, wide temp range, very
low dissipation, and tolerance to over voltage spikes. Many years
ago, I wasted a month working over an HF xmitter, trying to design out
the expensive silver mica and porcelain cazapitors and replace them
with cheaper ceramics. It was possible for the low power drivers but
a waste of time in areas that had high RF currents or required good
stability. A similar cost reduction exercise was also being done on
the automagic antenna tuner (by someone else) with similar results.
The project ended when someone suggested using high temp silver solder
to prevent the ceramic caps from reflowing their solder connections
and falling off the board.

I guess(tm) the reason that silver mica caps are difficult to find is
that there are few companies producing high power RF products as
compared to the huge number of low power RF products. It's not a big
market that probably can only support a few specialty component
vendors.

2412. best architecture for a homebrewed single-station FM broadcast dx receiver?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-23 17:19:41 UTC
From: alanh_27@yahoo.com
Message-ID: <c3prjd$b6f$1@xuxa.iecc.com>

Cross-posted to: rec.radio.broadcasting,sci.electronics,rec.radio.amateur.homebrew

a city I visit frequently -or more precisely, it's exurban outskirts - has only one mellow-Jazz FM-broadcast station, the only one for many hundreds of miles.

thus I have decided to build my own single-station hi-performance receiver to get the one station.

I know enough to know that ideally, the bulk of the gain, directionality, selectivity should be at the antenna itself. Or even more to the point, tower height. At least ideally. And hi-performance single FM channel yagi's are easily spec'd from a number of antenna houses. So that issue is not being placed on this table.

The rest of the gain budget is.

Let the discussions begin. For example, what approach do the known "name" receivers (Kloss Model One, GE Super Radio) use? can a homebrewer do better?
Which commercial house builds the best resonant chambers for the 108 Mhz frequency? Can be be done easily at home? how about the demodulation and audio portions?

...

In agreement and support of what Roy wrote, I'd toss out some
additional notes:

o I've seen (been the vicitm of?) silvered micas that exhibit random
tiny jumps in capacitance, which is a really bad thing in oscillators.

o You can get X7R dielectric SMT caps in SMT up to at least 0.1uF in
0603 size, for low voltage ratings. See manufacturers' data sheets
for the largest currently available values. I suspect reliability
suffers if you try to use ones with too high a C*V/unit volume,
though.

o As someone recently pointed out to me (Sphero, I think it was), you
can get C0G up to 0.1uF in SMT--I think he said in 1206 size.

o It's possible to get 1% C0G caps.

o A C0G is probably about the cheapest electronic component you'll
find with a maximum 30ppm/C temperature coefficient (though beware,
some C0Gs I've seen are rated up to 60ppm/C).

o There are special high-Q ceramics that are better than standard
C0Gs for use at microwave frequencies...generally above 1GHz.

Cheers,
Tom

Tom,
do you know any supplier of such for proto quantity ?
I need 1n/0805 and 4.7n/1206.
I can't find any of these and I feel I'll have to buy a handfull of 5%, sort
them and maybe adapt the resitors values to what the lot would kindly give
me.
Not very entertaining.

I have a bench full of equipment and use it only to get me out of the dark,
if no signal at all. Once I get past that, I use my own ears. I get far
better audio.
Instruments just don't cut it for "listening" audio. Lou

That's nothing. I got a better story..

Dad bought a pair of walkie talkies back in 1964 when I was 5 yr old,
I found the soldering iron (always watched him fix the tv sets for people)

and removed every part on the pc board from one of the wt !

When he got home, I thought he would whip my butt but instead
he gave me a big pat on the head and was proud of my work !

Thanks, Jeff and Ken, for the info about modern mica capacitors. I haven't dealt with the high-power RF world since a previous life as a radar technician, long ago now, so hadn't realized they're still preferred for some applications.

A aging G3 friend of mine would agree with you here. He seldom resorts
to anything more than a DVM and a capacitance bridge to carry out
quite difficult repairs. I, OTOH, am totally stuffed without a full
schematic, my 'scope, signal generator, frequency counter, spectrum
analyser and just about anything else you can think of. I once knew a
totally blind guy from Hastings who repaired radios without *any* test
equipment or schematics, seemingly by 'feeling his way around' the
circuit board and listening for appropriate responses. No way I could
ever do that: incredible. And I've met many others who have similar
abilities, too, over the years.

Hmmm...I simulated it, and it looked fine to me. I don't do a.b.*
groups. I haven't actually built one; more pressing things to do.
But I expect it will work OK. It assumes no inductive coupling among
the coils. That's usually not too hard to get low enough in practice,
if you orient the coils properly.

BTW, check out Coil-Q inductors for commercial RF coils in small
shield cans with decent Q. 7mm square can, Qu around 100 for
inductances and frequencies in the neighborhood we're talking about
here.

2427. Broadband tube driver circuit needed

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-23 22:43:57 UTC
From: Bob P <nospam@nospam.end>
Message-ID: <N438c.15252$t16.8617384@newssvr28.news.prodigy.com>
Source record: 27414

Want to have broadband (7-28 Mhz) 1 Watt (50 Ohms) class A solid state amplifier driving grid of 6L6 tube to about 2 or 3 mA grid current, tube is biased to about -65 Volts for class C operation with 550 Volts on the plate. I don't want to have any tuned circuits in the 6L6 grid if I can avoid it. As of now, the 6L6 has a 6CL6 driver feeding tuned grid circuit, easily gets 2-3 mA.
My goal is to eliminate the driver tube and the tuned grid circuit.

Anyone have knowledge of toroid(s) that might be required, turns ratio, material, etc.?
Do I need a more driving power ? Probably could get 2 Watts out of my driver circuit if need be.

thanks
Bob

Sorry to say that I don't have a recommendation for a vendor for small quantities of the 1% parts, but how many did you need? I know I have some of the 1.0nF 0805s, and might get lucky on the others too. I have a whole bunch of some value fairly close to 4.7nF, and I'm just not remembering which it is. Might be 3.9, might be 5.6 or 6.8, if not 4.7. Anyway, if you're not looking for too many, I'd be happy to help you out.

But even if you buy a bunch of 5% ones, that might not be a bad way to go. I just measured about 20 470pF 5% ones I happened to have on my desk, and they were between 468 and 488, about +/-2% from the midpoint.

I'm not remembering where I saw the 60ppm number. It surprised me, though, and I made a mental note to always check the specs on the caps I'm using, if it's important. It was fairly recently, and it was a surprise because I had always equated 30ppm with NPO/C0G. I just did a Google search for "C0G 60ppm" and got several hits, but in looking at some of them, I found 60ppm associated only with NPO, and not with C0G, so perhaps I'm wrong about C0Gs, at least. I'd be happy to be wrong in this case! A little further looking suggests that EIA CG or C0G officially must be +/-30ppm max, and EIA CH is +/-60ppm.

Cheers,
Tom

According to information I have, the C0 means zero nominal tempco, and the G means +/-30 ppm. There are various other letters (unfortunately not in order) representing tolerances from +/-10 to +/-2500 ppm. (There's also the letter O meaning "not specified" and P meaning "see applicable specification".) +/-60 is H, so a 0 +/-60 ppm part would be C0H, not C0G. This series of suffix letters is used for temperature compensating types (e.g., M7 (P100), R2 (N220)) as well, so R2G would be -220 +/-30 ppm, M7H would be +100 +/-60 pmm, etc.

My local electronics shop has it in more colors than that, along with
an assortment of tools.

I would suspect that Newark has it somewhere in their catalog.

WW is less used, there are other, newer, prototyping techniques out
there as well.

Some component leads still have the squared profile ideal for WW.

Happy trails,

Hey, give me a chance to keep up with your suggestions, will you? ;-)
I've only just today taken delivery of some powedered iron toroids you
tipped me off on (T37-10 for the time being) and am experimenting with
those at present. Moreover, I replaced the factory, miniature,
resistor-like inductors in my original 5X multiplier with hand-wound,
air-cored ones for better Q, and guess what? *Huge* difference!
Couldn't get a fifth *at all* before, as you may recall, but changing
the inductors for the higher Q construction really brought it on big
time! So much so I was convinced I'd made some fundamental mismeasure
with the test equipment settings. Eventually it dawned that there was
no error. The whole problem had been down to choice of coils - same
values alright, but very different Qs. I've you to thank most
sincerely for that revelation!
Though the transistor-based multiplier and buffer/amp now works great,
I'll still stick with your series filter solution as it saves on
transistors and other components too. Just one last query, Tom: in
your design between the ouput of the first inverter and the input to
the next, you have, in series, a 0-10pF variable cap and a 20uH coil.
Then you have your DC bias to the 2nd gate input and a 15pF cap
shunted to ground at the same point. What was the purpose of that 15pF
cap? Was it to provide an AC ground, bypassing the lower resistor (the
one from input to gnd) or was there some loading function involved
with it as well? Or was it intended to allow some independent control
over the signal voltage level to the 2nd inverter input?
Thanks again,

Paul

Hmm. 6L6 grid capacitance = 12pF (that's for a 6L6G - plain 6L6 is 10).
Broadband that up to 28MHz, you need the parallel R to be no more than 450
ohms (and that's for 3dB down at 28MHz).

Overall voltage swing > 2*65V; call it 140V, for an RMS of 50V. (50V)^2 /
(450*ohms) = 5.6W. Ignoring the grid drive . Assume that the coupling
circuit is 80% efficient, then you need about 7W.

The problem is that danged input capacitance. You can almost call out the
bandwidth from the constraints. You _should_ be able to make a circuit that
can be fixed-tuned for each band, you should be able to make it about 2MHz
wide if you size the coils right.

In This Power Play,
High-Wire Act Riles
Ham-Radio Fans

New Use for Lines Sparks
Tension With Operators;
'Firestorm' in Penn Yan
By KEN BROWN
Staff Reporter of THE WALL STREET JOURNAL
March 23, 2004; Page A1

Rick Lindquist drove down a street in a New York City suburb, ignoring the snow swirling around his car and twirling the dial on the ham radio mounted to the side of his dashboard. The radio picked up an operator in Minnesota discussing antennas, the Salvation Army's daily emergency network check and then the time, as broadcast from Colorado by the National Institute of Standards and Technology.

As the car turned onto North State Road in the village of Briarcliff Manor in Westchester County, the voices faded, replaced with whirs and wahs -- what could have been sound effects from a 1950s science-fiction movie. The source, according to Mr. Lindquist, was right outside the window: the power lines running alongside the road.

Owned by Consolidated Edison, the lines transmit not just electricity but data, much like phone and cable-TV wires. The utility is testing a system for reading meters, probing for outages and potentially offering high-speed Internet access to its customers via their electrical outlets. The interference from the power lines "ranges from very annoying to that's-all-I-can-hear," contends Mr. Lindquist, 58 years old, who often taps out Morse-code messages as he drives.

In a clash between the dots and dashes of the telegraph and the bits and bytes of the Web, the nation's vocal but shrinking population of ham-radio operators, or "hams" as they call themselves, are stirring up a war with the utility industry over new power-line communications. Hams have flooded the Federal Communications Commission with about 2,500 letters and e-mails opposing power-line trials. In a letter to the FCC, the American Radio Relay League, a ham-radio group with 160,000 members, called power-line communications "a Pandora's box of unprecedented proportions."

The league has raised more than $300,000 from nearly 5,600 donors since last summer, to pay for testing, lobbying and publicity to spread the word about the perceived threat. A half-dozen hams even confronted FCC Chairman Michael Powell, a big advocate of the power-line technology, when he visited a test site near Raleigh, N.C., earlier this month.

The problem, most ham operators contend, is that power lines weren't built to carry anything other than electricity. Telephone and cable-TV lines are either shielded with a second set of wires or twisted together to prevent their signals from interfering with other transmissions. But signals sent over electrical wires tend to spill out, the hams contend.

The FCC and the utilities say new technologies have eliminated the interference and accuse the hams of exploiting the issue for their own gains. "We haven't seen the sun darken and everything electrical turn to white noise and haze during a deployment," says Matt Oja, an executive at Progress Energy, whose test Mr. Powell visited. "This is a fairly vocal group that has been whipped into a frenzy by their organization."

The controversy comes at a sensitive time for the hams. Not too many decades ago, ham-radio operators were on the cutting edge of communications technology. They chatted with people in far-flung places at a time when long-distance calling was still a luxury. They spread word of disasters that otherwise might have taken days to reach the public. In the age of e-mail, wireless Internet access and cellphones that double as walkie-talkies, many operators worry that their hobby will fade away.

To become a fully licensed ham operator, people still need to learn Morse code, though that requirement likely will be dropped soon after more than a decade of debate. Aging hams, who built crystal radio sets as kids or were radio operators during World War II, are dying. Fewer youngsters are replacing them. Armed with powerful computers, today's young tinkerers grow up to be tech geeks, playing videogames and writing software.

The American Radio Relay League has seen its membership shrink to today's 160,000 from a peak of 175,000 in 1995, and the average member is in his mid-50s. The group estimates that there are about 250,000 active ham-radio enthusiasts.

Hams always have been a quirky bunch. They haunt a series of short-wave radio frequencies set aside for them by the federal government in the 1930s. Other slices of the spectrum are reserved for AM and FM radio, broadcast television, cellphones, and police and fire departments, among other uses.

Hams take great pride in radioing around the world. One favorite game: trying to contact someone in each of the 3,000-plus counties in the U.S. Mr. Lindquist is so enthusiastic about ham radio that he vacations in spots such as Whitehorse, the capital of Canada's Yukon Territory, so other hams can claim they made contact with that city.

Ed Thomas, the FCC's chief engineer, says the commission has spent a year listening to the hams' concerns about power lines and is getting frustrated. "Why is this thing a major calamity?" he says. "And honestly, I'd love the answer to that."

Companies such as Con Ed and Progress note that current FCC regulations call for systems to be shut down if they interfere with hams. The radio operators agree the rules are clear, but they fear they will be rescinded or not enforced.

Con Ed says its system in Briarcliff Manor doesn't interfere with the hams and maintains that, in two years of testing, it hasn't received one complaint. But the American Radio Relay League says it did mention this system in its letters to the FCC, and it has been complaining about it on its Web site.

The hams have been quick to act wherever systems are being rolled out. Just days after Penn Yan, a town of 5,200 that sits amid New York's Finger Lakes, approved a plan to test power-line Internet access, "the firestorm started with the ham-radio operators -- letters, e-mails, telephone calls saying, 'You can't do this,' " recalls Mayor Doug Marchionda Jr.

Hoping to keep everyone happy, he approached David Simmons, a local ham and owner of an electronics store that sells radio gear. They surveyed the town before the trial began to get base readings of interference. They even pinpointed a spot that had bothered police and firefighters for years, tracing it to refrigerators at a local supermarket.

With the refrigerators fixed and the power-line system in place over nine blocks of Penn Yan, Mr. Simmons is satisfied that there is no interference and now favors the new technology. "This thing has caught quite a buzz," he says. "It's just so much negativity out there."

Tom Gius, a ham-radio operator in Alpine, Texas, sees the power lines as a threat to the public services that hams provide. When hailstorms sweep through each spring, Mr. Gius heads to the local radio station, while other hams fan out to the north, south, east and west. They communicate by radio, and Mr. Gius passes information to the radio station. "We won't be able to understand each other, it'll be so noisy," frets Mr. Gius, a 60-year-old retired broadcaster.

Read the articles they link to on their site, arrl.org, about tests performed in other countries. Most countries that have experimented with BPL have abandoned it. I think BPL is just another scam. What does a power company know about running broadband networks? They couldn't even keep their own grid on line last year. They'll offer BPL at bargain prices to steal marketshare from DSL and cable. Then the service will go to hell and the prices will hit the heavens.

The difference between the U.S. and the other countries involved in testing BPL is, there are a lot of 1.5-kW stations in this country. Maybe after a few BPL modems melt down, the power companies will find other ways to gouge their customers.

Paul,

It's a series resonant circuit. The inductor is obvious. The capacitor is actually split between the one to ground at the gate input and the one on the other side of the inductor. Since it's a series circuit, the inductor and first cap can be swapped, of course; that might make it more obvious. The gate's RF input impedance (including a resistive part) and the bias resistors are in parallel (AC-wise) with the cap to ground, and provide a certain amount of damping -- lowering of the Q -- or the reason loaded Q is lower than Qu of the inductor. Since the tuning cap is in series with that cap, only part of the resonance voltage appears across it. Remember, in a series-resonant circuit, the voltage across the inductor or capacitor is much higher than the exciting voltage--that's where the voltage step-up comes from that's needed in this case. Splitting the net capacitance up this way lets you get a reasonably high loaded Q (to reject the other harmonics better) and control the output voltage, and provide the proper load at to the driving gate...as I recall, my design goal was about 100 ohms at the fifth harmonic, and a much higher impedance at the fundamental and the other harmonics. That way, the driving gate doesn't dissipate much power trying to drive those other harmonics into a heavy load, and only has to deliver significant power at the fifth harmonic. -- You could just use a cap from the gate input to ground, and an inductor to the driving gate's output (and then do away with the bias resistors too...), but then you can't so easily control the loaded Q.

Yes, you should generally consider more than just the inductance of a coil. Q and self-resonant frequency are both generally important. At high frequencies, coils are the least ideal of our linear passives: Rs, Ls and Cs. Usually you can get by with ignoring the non-idealities of film and composition resistors and the types of caps usually used at RF, but inductors are a different story. It's good preparation for working in the GHz range, where pretty much all components have non-ideal performance.

Cheers,
Tom

I don't find D0 listed in my reference. The only one I have with a 0 number is C0, nominally zero tempco. So if it is a legitimate capacitor designation, I don't know what it is. Getting kind of close to April 1, so maybe it's short for D0G B0NE, a kind of ceramic capcitor?

Followup on my previous offer: I have quantities of 3.9nF, 6.8nF and 8.2nF 1%, and a decent supply of 1.0nF 1%, but no 4.7nF rated at 1%. If I had the task of finding a dozen or two 1% 4.7nF parts, I'd just get a hundred 5% parts, make up a set of maybe ten bins (or just divide a sheet of paper into ten or twenty areas) in 1% increments, and sit down for about five minutes with my capacitance tweezers. The sorting goes really fast that way: pick up a part with the tweezers, read its value and drop it into the right bin.

Cheers,
Tom

I was talking (in person) to 3 UK hams at a gathering. All three of them
had Henry 2K amplifiers.

I think the answer about BPL is that European countries really do try to
control RF pollution. Even in the Caribbean, drive around the French
islands with an AM radio. I don't hear power line noise there.

The EU is very strict on EMI -- much more so than the US. Here we let in
all those 900MHZ chinese phones just so consumers have something to complain
about.

I wonder which will be worse, BPL or more unshielded and poorly designed
switching power supplies.

Before the walkie talkie disassemble, when I was about four I
found his tape measure. I could not figure it out how it worked,

so I took it apart by removing the four phillips screws that held the
case together. big mistake !

I was lucky and I almost poked my eye out when the spring
released from the case and hit me in the face!

No way could I put it all back in the case so I just shoved all
of it inside the toolbox and replaced the lock (easy to open with a bobby pin).

About a week later when he opened up that toolbox is when I got my butt whipped
!

So I guess the om cut me little slack with the walkie talikes.

> control RF pollution. Even in the Caribbean, drive around the French
> islands with an AM radio. I don't hear power line noise there.

Line noise also means wasted power and damage to components. BPL may, at least, get American power companies to clean up their acts.

As an aside, interesting to note that BPL is being flogged as the answer to the rural dweller's prayer, yet all the current offerings are in urban areas already served by DSL and/or cable broadband. If this FCC Chairman had a clue, he'd have arranged for BPL to be initially tested in places not served by other broadband services. By the time people wake up and realize BPL isn't the greatest communications 'revolution' since the smoke signal, it will have taken root and we'll never get rid of it.

OTOH, maybe ARRL can use BPL as a tool to continue fighting tower-height restrictions in residential areas. The farther you can get your antenna from the power lines, the better. How about power-company subsidized and installed towers? They've got the rigging equipment and crews, after all. Ie, BPL in every home = 120' + tower in every ham's yard. :>

Building a good receiver of any kind is complex, if you really want
good specs. Very few people have been able to accomplish this at home.
Just for calibration, you will require the proper instruments and
skills.

A good FM receiver with the proper antenna will do it, as long as the
antenna can see over the horizon, and within your distance range there
are no other stations at the same frequency. There are also the
physical limitations to consider as well.

Since the range of an FM station is about 120 to 140 miles at the very
best with a good antenna, there may be allowance for other stations to
broadcast within a 150 mile radius. If there are other stations, these
may be difficult to tune out.

You would be best off with an antenna that is cut to the frequency you
want to recieve, it will have to be able to see over the horizon
enough to see the transmitter site, have the proper directivity, and
be very well impedance matched to the receiver.

All the high end FM tuners are designed to be able to use an external
antenna, using a 75 ohm coax type hookup.

Have you considered calling this station to see if they are on the
net, satellite service, or on your local cable TV service? Many of
these small stations are on the net, and broadcast streamed
programming. This way you can use your computer to listen to them. '

...

Exactly what will make it "hi-performance"? I'd like to get this nailed down early here. That is, it would really help to know answers to things like:

What distortion performance do you want to get? (Will you be able to deliver a clean enough signal from the antenna to get to the desired performance level?)

What will the level of the desired signal be at the receiver antenna terminals?

What will the strongest unwanted signals be: level and relative frequency?

What resources do you have available for design, construction and testing?

Will this receiver be in a fixed location, or do you want it to be easily portable? How much power can it draw?

Others may well think of questions to add, before we go off into the weeds with unproductive answers.

Cheers,
Tom

You need to look at your particular situation. It sounds like you are out in the desert. Is this the case? Are there other strong FM stations nearby? Any others close in frequency?

Sensitivity is relatively easy to come by. The "best" audiophile receivers are more about selectivity, which sounds like it might not be an issue in your case. There is a similar issue with antennas. Directionality is there more to combat multipath then it is to get gain. Is the terrain flat? If you are between a lot of buildings then nothing you do at the receiver will make up for what you don't do at the antenna.

You are right about needing to get your antenna high, but for a single, point to point circuit, there is such a thing as high enough. More won't help. But less will hurt dramatically.

The other big problem is getting the signal from the antenna to the radio. At FM frequencies, line losses are significant, as is noise pickup. If the signal is marginal, then you need to get an amplifier at the antenna. If what reaches the receiver is mostly noise then no amount of sensitivity at the receiver is going to help.

At any given frequency there is only a certain amount of sensitivity that you can use. At FM broadcast frequencies, that amount of sensitivity is easily obtainable these days. You can probably do "better" in terms of sensitivity by building something, but you wouldn't hear the station any better ... in fact, probably worse by having too much of a good thing.

Yet another followup...

Mouser lists a few 1% values. You could give them a call to see if
they happen to have the ones you want. But the prices listed for the
1% values are so high I'd still consider selecting from 5% values, for
hobby work. (I'm reading this in r.r.a.homebrew, but I see it's also
crossposted to sci.electronics.design...so maybe paying a few dollars
each isn't prohibitive.)

Cheers,
Tom

Thought I posted a reply yesterday, but it doesn't appear to have made
it.

Before we head off into the weeds with all sorts of opinions, how
about some clarification? I'd be interested in answers to several
questions, and suspect others will add more.

o What sort of distortion levels and signal to noise ratio are you
wanting to achieve?

o What level of desired signal will you be able to deliver to the
receiver's input terminals? Will it be strong enough, and free enough
from multipath, to make the desired distortion and SNR practical?

o What levels and relative frequencies will strong potentially
interfering signals be? -- Let's hope there's nothing significant on
an adjacent channel, and nothing really big on alternate channels
(+/-400kHz).

o How skilled are you in RF and digital construction, and what tools
do you have available for design, construction and turn-on/alignment?

o Do you want the receiver to be portable and battery-powered, or can
it be relatively large and line/mains powered?

(o Why would you not just buy a good FM tuner, and perhaps just build
a preselector if alternate-channel stations were a problem?)

Cheers,
Tom

>

Don't be persuaded by an ill-informed WSJ reporter ... the amateur ranks are
not "shrinking"
... they've been growing steadily throughout recent history - though not as
much as *I'd* like.

Also, I can tell you from personal field tests and measurements that "access
BPL" is every bit
as bad as the ARRL indicates ... they are NOT "crying wolf" in ANY respect.

FEMA has also made a very strong statement against BPL and, while they
haven't released
their report yet, I expect that when they do the NTIA will also express
serious concerns/reservations
about access BPL as a threat to DoD, Homeland Security, and many of their
other Federal Govt.
"clients'" interest in, and reliance on, HF communications.

There is no "plot" at the ARRL "to raise money by stirring the pot vis a vis
BPL." If it were not for
the real and serious threat that BPL presents, they wouldn't NEED to raise
the money to defend
against it (or could raise money and use it for some useful purpose other
than defending our rights).

Many times articles in the press are way off base ... the WSJ one is one of
those cases, and I wrote
to the author telling him so and why ... I haven't received a response yet,
and may not, but maybe,
just maybe, next time he'll check his facts better before publishing such an
inbalanced and inaccurate
piece.

73,
Carl - wk3c

The local power line EMI person - whom I believe - says that the power lost in creating EMI is trivial. Anyhow the currents would flow in these loops even if there weren't a poor contact generating the EMI. He says even dirty insulators are a minor loss. The main economic advantage to the power company of fixing EMI is that it might indicate am impeding failure. As you say, BPL might induce them to clean up the EMI - or to turn up the wick on the BPL in the dark of night.

Google search for "wirewrap wire": first hit, RP Electronics, claims
to have it in stock in three colours, in 100 foot put-up.

Google search for "wire wrap wire": early hit, MarVac Electronics,
has it, probably in stock, in a wide variety of forms and colours.

Other hits are likely candidates as well.

Cheers,
Tom

That sounds interesting. I have used regular tweezers to slip sm caps into a fixture I made. This goes pretty fast except when I accidentally twang a part into some far and unknown location.

Did you make these youself? Can you give a quick description.

I can think how I could make low capacitance tweezers, but not how to flexibly connect them to a capacitance meter and get consistant readings.

30 gauge is the standard gauge for wire-wrap wire.
I've used it a lot for building up one-off circuit boards. This is by
soldering, not wire-wrapping. The insulation type does make quite a
difference if you solder it. I think Kynar is the one that works well.

Yup! However tube rectifiers don't like large caps. 10-20uF should be
enough.

If you need better regulation or hum reduction, use a higher tranny
voltage and a choke-input filter.

See http://www.hanssummers.com/radio/glowbug/psu/index.htm

I use a GZ33 rectifier valve, followed by pi-filter containing a 16uF capacitor, 5H choke, and 400uF capacitor.

I am no expert but from what I have learnt the following points are important:

1. The first capacitor should be relatively low value (my 16uF seemed about right). This capacitor should also be a very sturdy type, so that it is unlikely to fail. A less robust electrolytic in this location might fail and short out, destroying the rectifier valve in the process. Therefore I use an overspecified bipolar capacitor in this location.

2. Don't forget a bleeder resistor across the output, essential for your safety! This will discharge the capacitors within some seconds of switching off, making it safe to work on your equipment.

3. Small resistors (I use 55 ohm) in series with the rectifier anodes are needed to protect the valve from switch-on surge currents.

I also use a VR150/30 gas filled regulator valve to produce a 150V regulated output in addition to the 350V HT.

Wouldn't it be great if there were industry standard color codes for capacitors? But so far as I know, there aren't. I don't think there's any guarantee that black means NPO across all manufacturers, nor do I think there's a consistent meaning to orange and yellow.

>Do the formulas for solid state rectifiers apply??

Not quite. The voltage drop across vacuum diodes is
considerably higher and varies with different rectifier diodes,
typically 40 to as much as 100 Volts. You can find some
representative curves of DC output voltages versus AC input
for capacitor-input circuits in older texts of 40 to 50 years
ago. Some old vacuum tube data manuals give 'typical'
voltage drop values.

You can get an approximation for the peak DC output by
taking 1.4 times the AC RMS input, subtracting about 50
volts from that to begin a rectifier circuit for a 50 to 100 mA
HV supply. From there on you can pin down more exact
values with rectifier tube data.

A slight advantage of vacuum tubes in capacitor-input rectifier
circuits was that the very high initial turn-on surge isn't there;
a vacuum tube diode literally turns on slowly as the filament
warms up. In cheaper tube designs that was offset by the
higher heat dissipation of tube rectifiers creating a local hot
spot much higher than with semiconductor rectifier diodes.
[typical heat dissipation of a 5Y3 common dual-diode in 100
Watt units was 15 to 20 Watts all by itself]

For about the last 15 years I have been listening to NPR at 89.5 MHz while riding my bike for an hour or two on nice days. There are several locations where many radios don't receive and lose the station and sometimes capture another close station. I've been buying used portables at garage sales for $10.00 or less and comparing their performance. So far I haven't found any of the Walkmans or Sports radios that are acceptable and to date the best has been a Sony ICF-34, much better than my Grundig Yacht Boy 400, but I can't risk it to try my Sony 2010. I've built and/or modified many radios and often thought about trying to make a better 89.5 radio but I don't think there's anyway I can beat the commercial jobs especially when I can get them for $10.00 or less. Generally I prefer not to use headphones and instead fasten the portable to my handlebars so I can hear the radio and local sounds. The radios take a pretty good beating but few have failed from the vibration or minor crashes.
In the past I've lived in somewhat remote locations where I couldn't get the stations I wanted and the best solution was a good antenna with directivity and gain as high up as you can get it! But I can't do that on my bike.
However if you come up with a good home brew solution please let me know.

Check out the tube data sheets, available on several websites. If you need urls, I can dig them up. The RCA HB-3 books are online for sure.

> Do the formulas for solid state rectifiers apply??

Not directly, because tube rectifiers tend to have more drop than silicon. Different types have different drop, too, and it depends on the current load. An important concern in setups where the current draw varies (such as CW transmitters) is the voltage regulation of the supply from minimum to maximum load. Different types of rectifier tube have different regulation performance.

As a limiting case, with a full wave center tap rectifier using a transformer giving Vt volts on either side of center tap, the *maximum* voltage you will get is:

1.4 * Vt (capacitor input filter)
0.9 * Vt (choke input filter)

In real-life applications, the output voltage will be less.

The 6X5 is good up to 70 mA, but has relatively high voltage drop and relatively poor regulation. The 5Y3 is better, the 5V4 better still, and the 5U4 even better. The ultimate in tube rectifiers are the mercury vapor types, but that's a subject for another post.

What transformer do you have available, and what is the application?

btw, I have found that an input capacitor of 40uf is fine with the 5Y3 and larger rectifiers.

On a "dog bone" capacitor, orange = N150 (-150 ppm/degree C nominal temco) and yellow = N220. These are handy for compensating for the small temperature drift of a good toroidal VFO inductor wound on type 6 powdered iron, by using NPO for most of the tank capacitance, and N150 or N220 for the rest.

Go to Agilent home page, search for 16334A.

I also have a homebrew design that works fine, resolution to as little
as 0.01pF, but haven't had a chance to move it from the breadboard
stage to a more finished implementation. It will be tweezers that
connect to a readout box through a single coaxial cable (RG-174-type).
There can be interchangeable "heads" -- tweezers, spring clips, etc.
If/when I get enough round tuits to finish it up, I'll post/publish
something on it.

Cheers,
Tom

2481. varicaps in parallel

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-26 02:20:23 UTC
From: Ken Scharf <wa2mzeNOTTHIS@bellsouth.net>
Message-ID: <Y3M8c.9823$gZ3.2977@bignews3.bellsouth.net>
Source record: 27318

Some time ago, someone asked if they could increase the range of a vco by adding another varacap diode in parallel with the existing one. The answer given was that it wouldn't change the tuning range, since the min-max capacitance ratio didn't change. The answer sounded technically correct, but also counter to gut feel. As it turns out, it is only partly correct.

Consider using conventional tuning capacitors. Hammarlund used to make a line of double bearing variable caps in a range of max capacitance ratings. The principle difference between the family members were the number of plates. The 25pf variable would have had about the same min-max capacitance ratio as the 50pf variable. Yet ham lore had it that the 14Opf (well 140mmf in those days) would give a 2:1 frequency tuning range, and a 350pf unit a 3:1 frequency tuning range. In practice this did work out.

The reason is that it is the TOTAL capacitance across the inductor that resonates it to a given frequency. This includes the distributed capacitance in the coil, any stray wiring capacitance, and capacitance found in any parts (such as tube grid to cathode or fet gate to source) connected to the tuned circuit. If the inductor is fixed in value a 4:1 capacitance ratio is needed to give a 2:1 frequency range in a tuned circuit, 9:1 for a 3:1 frequency range (ie: capacitance ratio is the square of the frequency ratio).

Now consider a varicap tuned circuit using diodes with a 5:1 capacitance ratio (say 10-50pf). Our inductor has 5pf of distributed capacitance, and there is 10pf of stray wiring and other capacitance. We would thus have a 25-65pf tuning range or a ratio of 2.6:1 (not the diodes 5:1!)

If we were to add another varicap in parallel the diode tuning range would be 20-100pf, still 5:1. We now need a smaller inductor, so our distributed capacitance drops to maybe 3pf. The stray capacitance remains at 10pf. Now our tuning range is 33-133pf, a ratio of 4:1. Our original tuning ratio was 1.6:1, with the extra diode it would be 2:1.

So the original answer that adding another diode wouldn't double the tuning range is correct, but it would make some improvement.

2482. Unbuilt Heathkits!

There are quite a few on eBay, going for less than USD15 from the looks of
it. Go to ebay.com and search for "813 tube." You may as well keep it as a
souvenir.

Source record: 27333

Paul,

I am very reluctant to discuss this sort of thing on a newsgroup. It is likely to develop into a multi-post thread with sub-threads, aggravated by do-gooders and mischief-makers who imagine they know more about the program and coils than either you or I. Misunderstandings and aggro galore. The end result being inconclusive and a general loss of confidence in everything. And I venture to say, all this palaver when a bug in the source code does not exist - all being due to using a program outside its range of useability or some similar misunderstanding because I can't write the introduction to a program in the form of a book.

As I said in my e-mail which you havn't yet received, try sending me another test message as follows -

(1) Do not use my e-mail address as may be found in newsgroup messages.

(2) My correct e-mail address is g4fgq.regp@btinternet.com

(3) Ensure my address is correct in your address book.

(4) In the "To" line enter "Reg Edwards" without the inverted commas, and nothing else.

(5) In the "Subject" line use all capital letters and identify yourself.

This may help to distinguish your message from the 300 spam messages I receive every day. My service provider, the worst ever, doesn't help either.

Yours, Reg Edwards.

I'm not certain, maybe just a coincidence, but there's a Tom Gibson I know/met who's has some ties to Montana. He may have worked up there for some time. This fellow was also a maritime operator and is currently (I hope!) an officer on the museum ship John Brown (Liberty Ship in Baltimore). Last time I saw Tom was aboard last year. Might this be the same person?

I think they are listing ratings quite a bit less than the US 813.
The plate dissipation is over a 100 watts and they list the output
power as 100 watts. (0.1 KW). Course they may be running class A. I
think the ones I've seen were rated at close to 3000 volts on the
plate and on the order of 250 to 500 watts out depending on class and
duty cycle. I used to run the legal limit with a pair in grounded
grid. (Yup, tetrode in GG <G>). You could darn near read a newspaper
from the light off the plats.

One of the locals just picked up a pair for $10 or $15 each. OTOH that
is about the cheapest I've seen them.

As others have mentioned I'd watch e-bay and see what they are going
for.

Hi guys,

I have some surplus axial inductors marked as follows:

uH27 -K
GEL

I would have thought this implied 0.27uH or 270nH? GEL is presumably the maker. However, there's no resonance at 17.6Mhz with 300pF in parallel as might be expected of an inductor of that value. There *is* however, a resonance at 50.6Mhz., which implies that the inductors are actually 33nH. I'm confused. Anyone have any idea as to how to determine the value absolutely? Are makers' marking to be trusted at all?

I seem to remember the 5Y3 as directly heated which means it warms up before the rest of the valves in the set so producing high HT value intitially. Need to take this into account with electrolytics.

You might well be able to extend its frequency range downwards, too.
IIRC, it needs some very small 1 uF capacitors, which simply weren't
available when it was manufactured.

There is an associated transistor test set which is a walking disaster.

Source record: 27349

Paul,

I updated program SOLNOID2 to 3 because somebody had difficulty with defining the length of a coil as related to the number of turns when there are only a very few turns on it. Its a more complicated little problem than you might think. But the length of a coil, 1, the number of turns, 1, 2, 3 etc., and the winding pitch are all insisted on by the program.

So to clarify the point I rewrote the operating instructions. The program itself remained unchanged.

==========

You have been led up the garden path by the old wives. The L/C ratio has very little to do with the Q of a resonant circuit. Q is controlled independently by the losses in L and C. Since the loss in L predominates Q = omega*L/R.

The ratio L/C, everything else remaining unchanged, affects only the parallel impedance of the circuit. A high L/C ratio gives a high parallel impedance. You get a higher voltage gain in an amplifier with a high L/C ratio when the load is a parallel tuned circuit.

The parallel impedance is given by L/C/R = Q*Omega*L = Q/Omega/C.

Very often L and C are chosen from what you have in the bottom of the junk box.

Reg, G4FGQ

By comparison to semiconductor diode rectifiers, any tube/valve
diode type with hard vacuum is slooooooow to turn on. A solid-
state diode starts conducting as soon as forward conduction
voltage is achieved. That causes an enormous (relative) surge in
charging current for the input filter capacitor which, before turn-on,
had no charge at all. Given no load resistance at this point in
time, all of that charging current is flowing in that input filter
capacitor. If the primary power is applied at or near the peak of
AC voltage, the only thing limiting the current surge value is the
transformer total inductance and winding resistance, diode
internal resistance, equivalent series resistance (ESR) of the
input filter capacitor, and wiring resistance (negligible by
comparison). That can be one #$%^&!!! large current pulse.
For any sort of longevity, the solid-state rectifier diodes need to
be selected for their "safe" forward current surge ratings.

For a hard vacuum (as opposed to gas, like mercury-vapor types)
diode, even directly-heated, the initial diode "resistance" goes from
near infinity to near full conduction conditions in many cycles of
the AC input voltage. There is nowhere near the slug of current
at initial turn-on as with solid-state diodes. Tube diode rectifiers
can be classified as "gentle" towards input filter capacitors, so
much so that this surge current was seldom mentioned in older
texts. The conditions you highlight are a slightly different one...

In a tube rectifier, yes, a directly-heated cathode will apply the
full peak voltage quicker than the rest of a radio using indirectly-
heated cathode tubes. The initial load resistance is very high
and the input filter capacitor will thus reach the equal of the peak

AC input voltage. That's the major reason of having a Working Voltage rating of minimum 1.5 times the AC RMS input voltage (allowance for 10% over-nominal line voltage). Once the rest of the tubes warmed up, the load resistance dropped, and now the steady-state condition of the entire supply circuit could be assumed...and the DC output voltage dropped to design levels.

The major cause of failure in millions of 5-tube BC receivers other than tube filament burn-out, was the cheapness of the input filter capacitor. To improve profits of a very economical-to-buy unit, designers brought the working voltages of the (generally) cardboard tube cased electrolytic filter capacitors down to the minimum value. Few of those millions of BC receivers were designed for good heat dissipation...the total filament string dissipation was 17 1/4 Watts plus another 5 W loss in the half-wave diode tube rectifier voltage drop. The actual useable power (the "B+") was 15 W. That would be at least 38 Watts of heat dissipated in a small plastic enclosure. Those waxed cardboard tube cased electrolytics could only dissipate any internal heating (from ESR) through their wire leads.

More robust tube equipment used aluminum-can-cased electrolytics and large areas of aluminum chassis metal to help distribute the internal heating and dissipate it better. Designers used greater safety margins and increased the working voltage ratings of electrolytic and some other capacitors. With higher sales values of such specialized products, they didn't have to skimp on the parts in order to stay market competitive.

In more recent simple power supplies, you will still find some cases of input filter capacitor failures but the incidence of diode rectifier failures has also risen due to designers selecting diodes with lower surge current ratings (not necessarily due to economic reasons...more a case of not paying attention to it). The focus of failure reasons has changed over the years but it is still a rather more complex set of causes involved and not just in circuit design.

One thing I've observed over quite a while of pushing electrons around is that "old" tube-based equipment design talked overly much about voltage levels and neglected current flow things. [I used to be guilty of that but grew out of it due to smoking...of the equipment, not me...:-)] In more "modern" electronics in general, BOTH voltage and current have to be considered equally and basic circuit considerations can't get by with simple rules of thumb for tube circuits.

0.27uH is 5ohms at 5MHz.

Set to 5MHz and wind up your 50ohm signal generator to max output (say a
100mV or so). Measure it's voltage using the scope.
Short the inductor across the sig genny terminals and measure the voltage
across the inductor.
Ignore all irrelavencies such as phase angles, stray capacitances, Q factor,
series resistance,skin effects, self resonances etc. Just treat the inductor
as if it's a straight forward potential divider resistance in series with
the 50 ohms of the genny.

Eg. Sig genny open circuit output at 5megs is 100 mV peak-peak
Inductor connected and voltage measured is now 10mV peak-peak.
Therefore 1/10th of the available voltage is across the inductor and 9/10
lost across the genny internal 50ohms.
So inductor looks like 5 ohms therefore,
5ohms = 2 x Pi x 5megs x L?
=270nH. Simple !
Using this method it's easy to get down to the odd few nH.
Exact same method as used by a nice 'inductance meter' design that turned up
in Radcom about 12 years ago

regards
john

Bollocks.
Screwed myself by rushing for easy numbers

0.27uH is actually 8.5ohms at 5MHz

For the 10mv example L would actually be (10mV / (100mv-10mv)/50) =5.55
ohms, equiv' to 176nH.

Sorry!

I just wondered from a theoretical point of view what the program would
say about the harmonic content as you decreased the values you put into
it for t_r and t_f.

> What is not intuitive to me (and to others) is that harmonic energy
> of a rectangular waveform drops drastically by the 5th harmonic

> and is certainly lower than "obvious" numbers bandied about.

This is connected with my question. I am pondering why the energy
available for higher harmonics is less than for the fundamental and also
how your program works out this energy.

> But, also mentioned before by others is that shortening the rect-
> angular waveshape DOES increase the 5th harmonic, as evident
> by the approximate 12 db increase at 40 to 35 percent of the
> repetition period.

Its like pushing the baby on the swing in the park, you only need to
give it the occasional push or pull in the right direction. A 5f
resonator gets has to go for 2.5 cycles in between refuelling from a
square-wave (1:1) of frequency f.
With a mark/space ratio of 2:3 it looks to me as though the 'pull' on
the 5f resonator as the rectangular wave drops will take out all the
energy that was put in on the preceding 'push' - so no 5th harmonic. On
the other hand, 1.5:3.5 (30%) should be just as good for 5th as 1:1 (but
no better).
All that's assuming a zero t_r and t_f. In practice it must be that the
energy transfer to a resonator depends on these times. It seems that the
energy transfer is not so great to a faster resonator. Pursuing the
swing analogy, your arm has to move faster than the swing if you're
going to add to the swings energy.

> much as intuition would have everyone believe!

What do you mean by intuition here?
My intuition suggests to me that as the rise and fall times get shorter,
the energy available for the harmonics approaches that for the
fundamental. In other words, as a square wave approaches perfection it
gains the ability to stimulate all odd harmonic resonators equally - but
surely that can't be right. Possibly the energy transfer to a f and
(say) 5f resonator approaches the same value but the 5f resonator loses
5 energy at five times the rate of the f one, assuming equal Q.

The subistution book I have lists a replacement that has a 200 volt PIV and 200 ma current. If this is anywhere near correct it may be a little too much for a 1N914 to handle. The replacement is a RCA SK series . You may try a 1N4003 to 1N4007 if your voltage is over 100 volts.

The harmonic values will change, approaching that of an ideal
square wave. That's a truism. With zero rise and fall it IS the
same as an ideal square wave.

There's NO accurate little formula, saying, or myth that will
predict any particular harmonic value. That's the reason for using
nice, very quick number-crunching computer programs.

>> What is not intuitive to me (and to others) is that harmonic energy
>> of a rectangular waveform drops drastically by the 5th harmonic
>> and is certainly lower than "obvious" numbers bandied about.
>
>This is connected with my question. I am pondering why the energy
>available for higher harmonics is less than for the fundamental and also
>how your program works out this energy.

My program was developed while at RCA Corporation, specifically in
the time period of winter 1973-1974 using the core of three ideal
waveforms: rectangular, rising triangle, falling triangle. They relate
to a singular waveform using a time-delay formula multiplier so that
the rising triangle butts up to (in time) to the start of the rectangular
waveform and the falling triangle starts at the end of the rectangular
waveform. Entry is rise-time (the rising triangle), fall-time (the falling
triangle), and 50% amplitude pulse width which is the rectangular
waveform length and the length of the rising and falling triangles
adjusted for their inputted times. [draw it out to see it better]
Each basic waveform generates its own Fourier coefficient set. All
sets are simply added algebraically. Mathematically okay to do that.

A quick form of proof of that is to use a simple frequency-to-time
transform that works at each specified point in time along the
repetition period of the waveform. The original was a time-to-
frequency transform, mathematically different than the opposite.
If a reconstruction of the frequency-to-time results in the original
entry specifications, then it is called accurate enough. I didn't
derive the reconstruction transform since it was already in a book.
Neither did I derive any of the basic ideal waveforms which were
already in the ITT Blue Bible. The delay multiplier used to set
rise, fall, and 50% width was another book value, simplified to
faster calculation simplicity because the original was a math
problem thing with more terms than needed.

As to WHY of the energy distribution, that's up to any person who
has the textbook formulas and math smarts to fool around with.
I can't sum that up in one message. I doubt anyone can. I do
know this: Using the formulas and the program, then setting up a
test with careful adjustments of a pulse generator and using a
well-calibrated spectrum analyzer, the numbers agree within the
tolerances of the analyzer calibration. To me, and lots of others,
that is all the proof needed. Beyond that, its too much time and

nobody paying me to do this...

>Its like pushing the baby on the swing in the park, you only need to
>give it the occasional push or pull in the right direction. A 5f
>resonator gets has to go for 2.5 cycles in between refuelling from a
>square-wave (1:1) of frequency f.

Use any analogue you want. I don't agree with the above, but
feel free and I not going further on that...

>What do you mean by intuition here?
>My intuition suggests to me that as the rise and fall times get shorter,
>the energy available for the harmonics approaches that for the
>fundamental. In other words, as a square wave approaches perfection it

For any ideal rectangular shape, the harmonic energies have a
(SinX / X) locus. That's explained in textbooks also. Harmonics
of a repetitive waveform Fourier transform will NEVER have more
energy than the fundamental. That's also basic book stuff.

If the rise and/or fall times are finite, the harmonics will drop their
energy levels compared to the zero rise and fall time ideals. As the
rise and fall times get longer and longer the harmonic energy gets
less and less. By the time one gets to a sinusoid waveshape,
there are NO harmonics in any Fourier transform, its all
fundamental frequency (1 / repetition-period).

Recess.

OK. I'll just say that on reflection I realise that it's not an analogy
- it's a bona-fide case of extracting a harmonic from a repetitive pulse
waveform.

I'm talking intuition not Fourier.
BTW your earlier comment on shortage of energy at higher harmonics may
be exacerbated by the lower Q of LC resonators at higher frequencies.

> I would think not, but I don't know why.

There are two parameters specified, but you are reducing them to one. The first is the current, the second is the voltage. With a non-reactive 50-ohm load, the rf current at 1000 watts is about 4.5 amps, and the rf voltage is 70.7 V. These formulae are in every edition of the ARRL Handbook. See also the Handbook discussion of skin effect. At higher frequencies, ac tends to travel near the surface of a conductor. If the relay contacts are silver plated, this may not be a problem. The contacts in the old Dow-Key coax relays weren't very large; it doesn't take a fat relay to switch non-reactive 50-ohm loads. If you want to switch high-impedance or badly mismatched antennas, you may exceed the capability of the relay. Another consideration is whether you will actually be hot-switching the rf. If the contacts are closed before rf is applied, there is less likelihood of arcing and damaging the contacts.

Relays designed for rf use are mechanically constructed to minimize impedance variation through the contacts, to maintain the non-reactive 50-ohm impedance of the system. At HF, a slight impedance 'bump' is not a big deal. For amateur HF use, this relay will probably do the job.

At a low impedance point in the line they could be ok. If you are going to use it for switching in and out an amplifier after the rig probably no problem. If you are depending on it for some isolation such as a low level preamp then it will need to be sjpecified for how much isolation it has. If used as an antenna switch you need to check the voltage rating so it will not arc over in a high impedance point. The contact spacing and internal wire spacing may give a problem in some situations. It all depends on the relay.

I'm not sure of anything! These small inductors are notoriously
difficult to measure accurately. Even lab-grade kit can differ in
measured values by as much as 100% or more and the risk of parasitic
resonances is an additional problem. :-(

In article <4066D5DD.77BD@virgin.net>, Peter John Lawton
<peter_john.lawton@virgin.net> writes:

>I'm talking intuition not Fourier.

"Intuition" is a subjective term but generally applies to "seeing"
a direction of some change after one has worked with a subject
for a while. Thirty years ago I had access to an RCA Spectra
70 mainframe and time on-line to do a lot of work with shapes
and their harmonics. The PC on this computer desk here has
MORE computing power and more mass storage and better
input-output than a half room full of mainframe back then.

>BTW your earlier comment on shortage of energy at higher harmonics may
>be exacerbated by the lower Q of LC resonators at higher frequencies.

IN a particular circuit, yes. But, to get into a new area, one
should start with the basic conditions. For a repetitive wave-
form, the Fourier Coefficient formulas are fine to establish the
energy distribution over frequency...in an ideal system. After
that, the individual conditions of a non-ideal, realistic
application can be applied.

Whether or not there are losses of higher frequency energy
depends also on the type and value of an inductor...small ones
might actually have highest Q at the desired frequency and
that changes the relative power distribution at circuit output.
Intuition in this case raises a little mental flag to check Qs of
actual, available parts to see if they will work better...or not.
The same intuition would also flag me to check out the f_t,
the transition frequency of the bipolar expected to be used;
Too low an f_sub_t would mean a greater loss of higher
harmonics at circuit output. Maybe I could select a combo
of the two so that things evened out? Okay, that and about
a dozen-plus things need to be checked in the planning
stages and "intuition" may or may not help. That depends on
one's past experience in cranking on specific things.

"Intuition" can also lead one astray. Ever hear someone say
"You can't do that!" in response to explanation of some new
thing that another has already done successfully? :-)

>it will take 1100 watts. Will it take 1000 watts of RF?
>
>I would think not, but I don't know why.

Relay CONTACT ratings have little to with relay COIL ratings.

Contact ratings assume a specific environment such as AC
primary power circuits, 28 VDC aircraft distribution, etc. That
is for the overwhelming majority of relay applications. In the
case of contacts rated for 115 or 230 VAC applications, those
will have open-contact spacings larger than lower-voltage DC;
spacings are generally designed to withstand about 3 times
the AC RMS voltage specified in ratings. Generally, but
not always.

To switch RF in a coaxial line system you have to allow for
the VSWR having a high value...choose at your own
convenience for expected conditions. The reason for that is
because, at a high VSWR, the relay contacts may be at a
maximum voltage point or a maximum current point.
Depending on the VSWR, either maximum may exceed the
contact ratings values. Location of either maximum depends
on frequency, length of transmission line, velocity of
propagation of the line used, antenna characteristics, and
the distance from the discontinuity (typically the antenna
feedpoint).

There are many tables and nomographs in ham literature to
determine the maximum voltage or maximum current with a
given SWR for a given characteristic impedance of a line.
A realistic worst-case value should be selected to avoid
having to replace a relay often due to arc-over or contact
sticking due to maxima. If an RF system is perfect (1:1
VSWR, line Z exact and unchanging) then compute the
required voltage and current from ordinary Ohm's Law.

I have yet to see such a perfect system but I know others
claim them as such... :-)

It will take 1100 watts at 110 volts. But if you lower the voltage to, say, 50 volts, and the contacts are still rated at 10 amps, it can only handle 500 watts. Etc.

>Will it take 1000 watts of RF?
>
>I would think not, but I don't know why.

Depends entirely on the RF characteristics - impedance, SWR, etc.

The trick is to exceed neither the voltage nor current ratings of the contacts. In a 50 ohm RF application with low SWR (less than 2:1), that relay is probably limited by its contact voltage rating, not the current rating. Which works out to about 200 watts.

From: Nick Kennedy <wa5bdu@yahoo.com>
Message-ID: <106eumsfhqpgf39@corp.supernews.com>
Source record: 27372

OK, but remember that the voltage drop across the inductor plus that across the source resistance don't add directly to the source voltage. With your example of 10 mV across L and 100 mV open circuit voltage, the voltage across the 50 ohm source resistance is 99.5 mV. That's because they're 90 degrees out of phase and add in a right triangle fashion.

Maybe you considered that, and that's why you chose a small value of drop across the inductor. When that's the case, the hypotenuse and x-side of the triangle are pretty close to equal. But users of this method need to understand this simplification and the implied restrictions.

I've used something similar to measure the inductance of chokes too large for my meter, such as transformer windings and power supply chokes. You can put a known resistor in series with the choke, put 60 Hz AC across it, and measure the two drops. Then calculate the inductance using a method similar to what you've described. But keep the sum of squares relationship in mind. (Supply voltage squared equals drop across resistance squared plus drop across inductance squared.) If the inductor has significant resistance, it should be added to the value of the series resistor.

2538. Ameco AC-1 revived

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-29 05:47:23 UTC
From: Uwe <outhouse@midcoast.com>
Message-ID: <BC8D229F.31A8%outhouse@midcoast.com>
Source record: 27375

With the help of some folks here I did troubleshoot my AC-1 tube transmitter (using a 6V6) and got it working somehow. Since I passed my code test and had my first QSO using the transmitter and boy was that exciting.

But questions remain.

I monitor the output signal on my scope and notice that right after key down the waveform contract just a bit and the tone changes pitch. I guess this is called chirp. I normally use B+ 200V.
If I increase the voltage lets say to 300V this effect becomes much more pronounced.
I still use an external bench supply capable of much higher currents and I don't think it is a power supply weakness. In fact putting a VOM on the supply line shows no sag in my supply voltage.

How can I minimize this and especially keep it from becoming more severe at higher outputs.

Also, the circuit diagram for the tranmitter did not state the coil diameter of the pi network. The pi network still has me scratching my head. Coils with slight variations in diameter give dramatically different results.

Also changing the air cap with one of an identical range can have a vast effect, which surprised me. Is this the "real world components" versus the theory???

Uwe

<< I monitor the output signal on my scope and notice that right after key down the waveform contract just a bit and the tone changes pitch. >>

Uwe-

I can think of two reasons for the "chirp".

You did not mention your receiver. It is possible that the strong signal from your nearby transmitter causes the receiver to change pitch.

I assume your transmitter is crystal controlled, since that is similar to the 6V6 homebrew transmitter I started with back in 1955. By increasing voltage, the crystal current increases. There is an effect due to heating of the crystal that might cause a chirp.

In the case of my old transmitter, I found that I could get more power output by changing the 6V6 to a 6L6, which has the same base diagram. However, one thing that happened along the way was that crystal current increased to the point that one of my crystals fractured and stopped working.

Looking back, I realize that the increase in power by changing tubes and increasing voltage, may not have made a significant difference. If you double your power, the received signal only goes up half an S-Unit. Improving your antenna can make a bigger difference!

I don't know about the waveform contraction. I doubt it is from overload of the scope, but it might be due to the tube being a little "soft" due to low cathode emission in the 6V6.

Congratulations! Though it's been many years, I still remember when I made my first contact with a transmitter very similar to yours. (It was 1954)

As for the chirp, this is partly the nature of single tube transmitters. You can minimize it with careful power supply design, and just the right amount of feedback on your oscillator, but a small amount will remain.

The feedback is controlled by the ratio of the capacitors marked C7 and C9 in the original Ameco schematic. They form a "tap" on the cathode RF choke. Increasing C7 slightly or decreasing C9 slightly will increase the feedback. Different crystals will also react differently.

I think 200 V is enough. Someone here probably knows what the AC-1 design voltage was, but I'm sure it wasn't 300 V, and may be have more like 150 V. While the 6V6 can handle higher voltages, as a keyed crystal oscillator, you don't want to overdo it. You could fracture a crystal, too.

There's quite a bit of AC-1 lore online. Use http://www.google.com/search?q=ameco+ac-1 to find it. I even found a copy of the original AC-1 manual, but it doesn't show circuit voltages.

Congrats on getting your ticket and making your first QSO. Now it's time to put this antique away and build some safe, cool, solid-state gear!

I disagree somewhat. There is a lot to be learned from simple gear, tube or otherwise. Tube gear is more forgiving of the mistakes we inevitably make while learning. It will also bite you if you are not careful, so you learn respect. He should try the classic 6CG7 807 transmitter next - a bit more power and a lot less chirp.

It can be a lot of fun making contacts with this kind of simple equipment, and it improves your code proficiency to the point you might even decide code is fun.

I don't have the schematic, but if the screen voltage comes from the
usual dropping resistor & bypass cap then it is probably dropping a
little bit under load. This will cause the plate current & output power
to fall a bit, and change the operating characteristics enough to chirp
a little bit.

As mentioned by another poster, this is the nature of a single-tube
transmitter (or single-anything power oscillator, for that matter). No
matter what you do the amplifier characteristics will be different for
different RF outputs, so the frequency _will_ change. You can minimize
it but you can't make it go away.

>
> How can I minimize this and especially keep it from becoming more severe at
> higher outputs.

Several things to check:

1) If the receiver you are using to monitor the signal is overloaded
by the strong local signal, it can make the signal sound like it is
chirping or clicking even if no such chirps or clicks actually exist.
This is particularly true if the receiver isn't really meant for CW
use. What are you using to listen to the transmitter's signal?

2) Besides the power supply, chirp in that sort of rig can be caused
by:

a) the crystal - try a different one if you can

b) the feedback capacitors (the one from the grid to cathode, and the
one from cathode to ground). These control the feedback in the
oscillator, and if there is too much or too little, chirp can result.

c) the 6V6GT tube - try a different one if you can

d) output tuning - maximum output is often not the best setting for
chirp.

> Also, the circuit diagram for the tranmitter did not state the coil diameter
> of the pi network.

It's 1-1/4 inches.

> The pi network still has me scratching my head. Coils
> with slight variations in diameter give dramatically different results.

That's to be expected.

A common formula for the inductance of a solenoidal air-core coil is:

L = (a * a * n * n)/ ((9 * a) + (10 * b))

where

L = inductance in uH
a = radius of coil winding in inches
b = length of coil winding in inches
n = number of turns

>
> Also changing the air cap with one of an identical range can have a vast
> effect, which surprised me. Is this the "real world components" versus the

2549. Omni Antenna question please?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-29 22:29:35 UTC
From: Bob <nubob5001@yahoo.com>
Message-ID: <qC1ac.10073$R37.9874@read1.cgocable.net>
Source record: 27387

Hi

I was given a Omni antenna from a ham who claims the best thing since sliced cheese. I want to use it for receive at first and when licenses come in for transmit. I would like to transmit on as many frequencies as practical and possible as I have a good tuner.
This is an omni, aluminum, telescopic and it 19 feet long. It has 4 ground planes about 8 feet long.
As I was cleaning it up, I noticed a coil at the base of the antenna connecting ground to center. Right at the female connector within the base of the antenna. There is a coil that has approx 20 windings and connects to ground. The center also feeds to the piping that stretches the full 19 feet. The coil is pretty rough shape.
My question is in regards to this coil. Is it necessary? What function will it serve? I can rebuild it if need be but is that necessary? And is 19 feet a good length for utilizing as many useable frequencies as possible?
Any advice?
Thanks
Bob

I have Dixon's text on spread spectrum techniques, but that's perhaps
Too Much Information. The TAPR has a book out on spread spectrum in
ham radio, which may be more to the point. Have a quick look at
<http://www.tapr.org/tapr/html/Fpub.ss.html>.

And of course a google on `"Spread spectrum" book` will give lots and
lots of hits on textbooks.

But as for synchronization, you have to know roughly where in the
FH or PN sequence the transmitter is, and then adjust your receiver
clock to sync up, and then do early-late tracking to keep the RX clock
synced up with the TX clock.

If I were doing it, I'd always start at the beginning of the FH or
PN sequence for each transmission, and build my receiver to expect
the TX to do that. Otherwise it starts looking too much like crypto
for me to want to deal with it.

The Eddystone 898 is, without any question in my mind, the ultimate tuning dial. It is also the most difficult to work with (it's output shaft is elevated rather high) and the most expensive.

Hi Bob,

You need to ask the 'Ham' two things,
What type of antenna is this and for what frequency?
What is his call sign?

Just a guess, but it sounds like a 10 meter 5/8 ground plane.

Chris

Yes, I think it was originally a omni three or four band antenna with traps
all the way up. He removed the traps and used it as a single whip.

What about that coil? It is a copper winding of about 1/16" copper wire that
is about 1" diameter.
Is that coil required or should the connection be a straight through
connection with no coil tapping to the ground?
Thanks

Not really. The original design uses about 300-325 volts.

>Someone here probably knows what the AC-1 design
>voltage was, but I'm sure it wasn't 300 V, and may be have more like 150 V.

Check the power transformer - it gave at least 300 volts with the 6X5
rectifier specified.

The AC-1 was spec'd at 15 watts input, which means about 40 mA at 350 volts!

>While the 6V6 can handle higher voltages, as a keyed crystal oscillator, you
>don't want to overdo it. You could fracture a crystal, too.

I ran a similar transmitter as a Novice. 350 volts on the plate of a 6V6GT,
grid-plate circuit. Xtals were fine, both on 80 and 40 meters. Those were
FT-243s, though. Smaller xtals need a bit more care.

A 6AG7 is a lot easier on the xtal than a 6V6.

Why? If it does the job, what's the problem?

As another poster commented, the next step is a classic 6AG7/807 MOPA design (or similar tubes - lots of choices, like the 6BG6, 6DQ6, 1625, etc). With a few more parts than the AC-1, you can get 40-50 watts output. And learn a lot in the process.

If you're building the classic HBR-16 and you don't want to modify the front end layout, then *the* dial to use is the Eddystone 898. Also keep an eye out for the Millen 39016 coupler (special type that has no backlash and tolerates misalignment) and of course a suitable tuning capacitor.

While 898s have drawn amazing prices on eBay in the past, (well over $100) recent sales have been quite a bit lower. There are two of them on auction right now, and two closed last week. (insert standard disclaimer here).

This is something I thought of building several times, but with extensive modifications. I just don't care for the classic superhet with the first oscillator a vfo. This requires calibration of each band, and also tracking adjustments. I prefer the variable first IF and a crystal controled first oscillator. (Like the drake 2B). My idea of a receiver project would be to add an additional rf/mixer front end to the HBR with a first if of 3.5-4.1 (and 6.9-7.5). The second IF would be 1.7khz (so it's an 80/40 band image front end). The final IF would be 85khz (guess where those IF cans came from). Being a compactron nut, the front end would use a 6AR11 rf amp/mixer, and the 85khz IF would use another 6AR11. A 6AV11 for the product detector and bfo, 6AF11 for the AF stage and agc amp. Other tubes for the rest of the rig TBD. Also thought of using toriods in the front end and bandswitching them by mounting them in a standard turret tuner chassis ripped out of an old TV set. (I've got some real old junk in my junk box!).

I have several ARC-5 rx three gang variable
caps, these have a real nice vernier drive on them. Just attach a larger dial, or a drive pulley for a slide rule dial and you have something as nice as the Eddystone.

(I sold an Eddystone I had in the junkbox a few years ago on ebay, it fetched about $130 IIRC. Nice dial, but a RPITA to cut out the front panel and mount correctly.)

W7WKR was doing some experimenting in that area a few years ago (w/FCC permission), and likely would share some info. I don't have his email address handy, but perhaps you can find it with a search.

Since very accurate time is available, it should be possible to get close in the sequence. A typical way to lock onto pseudorandom things is through correlation. But how do you optimize things when there's fading and very weak signals to begin with?

Cheers,
Tom

That introduces problems because that wide 1st IF encourages
intermodulation unless you really ride the gain budget. The Galaxy V
avoids this by using single-conversion with a 9MHz IF. It uses a single
5-5.5MHz VFO that's premixed with the crystal oscillator output for all
bands except for 20 and 80 (and 20 tunes backwards, in traditional 9MHz

IF fashion).

The '88 ARRL handbook had a spread-spectrum project. You'll need to
find a buddy to implement one, too.

And your point brings up that once you start modifying something, it's
not the original.

I've seen some of the HBR articles, and followup letters, and the author
did make comment about people "making receivers just like mine, but with
a few changes...". He made the point that he had put effort into making
receivers that not only worked, but could be duplicated, and once someone
started messing with them it tempted problems. One reason they were
popular (though I have no idea how that translates to actual figures)
was that the author had put so much effort into it all, and if I'm
remembering, there were extras like chassis layout patterns that
could be had for a nominal fee.

To some extent, I question building one today. Not only is there
the issue of getting the specific parts, but receiver design has
changed a lot. Are they double conversion? I can't remember, but if
so, they used a fairly broad section at the first IF, before dropping
to the final IF and it's selectivity. There was good reason forty
or so years ago to use such a design, but that hasn't been true for
a long time.

Putting a converter ahead of a tuneable receiver had reason years ago,
but that too has changed.

And if one is going to shift the conversion scheme around to make
it a converter into a tuneable receiver, one might as well start
with any of the numerous designs that did just that.

Of course, there can be reasons of nostalgia for building one,
in which case the tracking down the parts becomes part of the
process, rather than an impediment to building a receiver.

Well it mainly depends on what frequency you want to use it on. Removing
the coil will electrically shorten it, thereby raising the frequency. You
should ask the guy you got it from what frequencies he used it for, or else
use an antenna analyzer to see where it is resonant.

Well, the nice thing about spread spectrum is that it effectively integrates all that under-the-noise signal and produces something with a lot more amplitude. And yes, the autocorrelation properties of the PN sequences are very important in synchronization: the output of the correlator is something close to 1/n for out-of-sync and 1 for in-sync.

The difficulty is knowing roughly where in a long sequence to start the search, and that's why the military GPS receivers use the C/A (Coarse Acquisition) signals to get the Precise Positioning Service parts of the receivers in the ball park. Once they've done that, it's the same old game: slew the clock and look for a jump in the output of the correlator.

I've searched in vain for the above value cap's.

Would accept a couple in series or parallel to get to the above minimum.

I require two in total.

Would anyone have something similar of good quality that they would be
willing to sell?

Tnx

All of those things can be dealt with. To me the big problem with the
basic HBR design is the stability of the tunable HFO.

> I prefer the variable first IF
> and a crystal controled first oscillator. (Like the drake 2B).

Me, too. There are some pictures on the HBR site of a receiver I built
about 30 years ago using that principle. It worked very well, and cost
me almost nothing to build.

> My
> idea of a receiver project would be to add an additional rf/mixer
> front end to the HBR with a first if of 3.5-4.1 (and 6.9-7.5). The
> second IF would be 1.7khz (so it's an 80/40 band image front end).

In the 1965 ARRL Handbook there is a receiver described (the HB-65)
which is almost exactly what you are describing, except it used the
100 kHz Miller IFTs. The 85 kHz cans are probably much easier to come
by these days.

> The final IF would be 85khz (guess where those IF cans came from).

Swords into plowshares...

> Being a compactron nut, the front end would use a 6AR11 rf amp/mixer,
> and the 85khz IF would use another 6AR11. A 6AV11 for the product
> detector and bfo, 6AF11 for the AF stage and agc amp.

Nothing wrong with Compactrons, but you are begging for trouble with
that scheme because the layout and section-to-section stray
capacitances will make it difficult to isolate the various stages. The
skirt selectivity of the IF amp will be compromised as well. The
layout will also be a compromise.

> Other tubes for
> the rest of the rig TBD. Also thought of using toriods in the front end
> and bandswitching them by mounting them in a standard turret tuner
> chassis ripped out of an old TV set. (I've got some real old junk in my

The basic idea is very sound if the Compactrons are used differently.

> I have several ARC-5 rx three gang variable
> caps, these have a real nice vernier drive on them. Just attach a
> larger dial, or a drive pulley for a slide rule dial and you have
> something as nice as the Eddystone.

Yep! Note, however, that except for the 6-9.1 MHz version they have plate shapes that won't yield a linear dial on the ham bands. The 6-9.1 MHz version is almost pure straight line capacitance, and is only 62 pf per section or so.

For the ultimate, though, use the capacitor from an ARC-5 tx, BC-221 or LM freq meter. Nice gear drives and an even bigger dial than the rx versions. Only one section though, but good for "unit oscillator" construction of the HFO. (Only needs to cover the range 5.2-5.7 MHz)

With such a design, it would be a good idea to use a Pullen mixer and no RF stage in the 80/40 bandimage section (at least). There's also the problem of secondary images - you need a lot of selectivity in the front end and 1.7 MHz IF section to avoid signals 170 kHz from the desired one seeping into the second IF. The 2B used a 455 kHz first-fixed-IF for this reason. IM performance is compromised by the fact that the selectivity is so far from the antenna.

Some alternatives to consider:

1) Get some xtals in the 1700 kHz range and build a filter or filters so that the 85 kHz IF is not needed. Perhaps a variable-bandwidth filter using a multigang variable capacitor could made, using 4 crystals and a three-gang capacitor. This approach solves the secondary image problem, too.

2) Have a single tuning range of 3.5 - 4.1 MHz and the fixed IF at 455 kHz or thereabouts. Would require dual conversion on 40 but would also allow use of standard 455 kHz IF filters. Or make your own from FT-241A crystals (which is what I did way back when).

3) Use the filters and heterodyne xtals from a junked transceiver as the basis of a homebrew rx. Hangar-queen/basket case HW-100s, -101s, and SB-line units show up on ePay and at 'fests for quite low prices - far below what the filters and xtals would cost separately. Other types of transceiver can also be good parts sources (Tempo One comes to mind - nice VFO mechanism in them, and the IF is 9 MHz IIRC). KJ4KV turned an early-version FT-101 into a pretty interesting receiver this way.

Besides the HBR website, the HBR reflector offers receiver ideas that range far beyond the classic W6TC HBR series designs.
>

I haven't used an 898 yet but with the template (which I have) it shouldn't be too difficult except for that huge rectangular hole in the panel.

So many great hollowstate rx ideas!

Agreed! However, there's something to be said for both the exact copy
and modification approaches.
>

> started messing with them it tempted problems.

But OTOH some of the mods turned out to be very worthwhile, such as
the 898 dial on the HBR-16 and the product detector mods. There were
also some problems that were only shaken out by the construction of
many copies.

> One reason they were
> popular (though I have no idea how that translates to actual figures)
> was that the author had put so much effort into it all, and if I'm
> remembering, there were extras like chassis layout patterns that
> could be had for a nominal fee.

Yep, a whole packet of photos, layout templates and other stuff could
be had.

Another point was that the HBR series were designed around
then-current-production parts obtainable by mail order. A builder
could get every needed part that way, if necessary, and some did just
that.

> To some extent, I question building one today. Not only is there
> the issue of getting the specific parts, but receiver design has
> changed a lot.

Agreed in part. But within their limitations they are a sound design.
And if you can get the parts, they are "duplicatable" with limited
tools and test equipment.

> Are they double conversion? I can't remember, but if
> so, they used a fairly broad section at the first IF, before dropping
> to the final IF and it's selectivity.

They used a first IF around 1700 kHz (for decent image rejection on
all of HF with only one RF stage) and a second IF at 100 kHz.

The first IF isn't as broad as you might think, particularly in
versions that used two IFTs. Certainly it's much narrower than the
tunable-first-IF designs that followed.

> There was good reason forty
> or so years ago to use such a design, but that hasn't been true for
> a long time.

The 1957 QST article "What's Wrong With Our Present Receivers" pretty
much makes the case for the use of single-conversion and xtal filters
in the low-HF range. The 1965 "Miser's Dream" receiver demonstrated
the principle, but was not a wire-for-wire "duplicate me" article. And
the filters weren't cheap - 1959 price for the Hycon Eastern 2215 kHz
filters was $44 *each*.
>
> Putting a converter ahead of a tuneable receiver had reason years ago,

The HB-67, in the ARRL Handbook of 1967, for example.

> Of course, there can be reasons of nostalgia for building one,
> in which case the tracking down the parts becomes part of the
> process, rather than an impediment to building a receiver.
>
I approach the challenge the other way: Look at the readily-available
parts and see what can be built with them. Of course, "readily
available" varies with the builder!

But there's nothing like getting on the air with a 100% homebrew
station. Even kitbuilt isn't quite the same.

[clip]

Yes. This is true. Keep the O/C S/C ratio as wide as you're happy with.
Fortunately this is usually easy to do and the method allows a quick and
(slightly) dirty measurement without the extraneous baggage that
accompanies other methods. I built an (accurate) test unit using this method
that goes down to a FSD of 300nH and though I have a digital LCR bridge the
homebrew item is *always* used to give final conformation and confidence in
an L's value. Measuring an inductor somewhere near it's operating frequency

is essential.
You clearly understood where I was coming in from on this topic. The usual reaction is some kind of patronising look and words like "you can't do that, don't you know anything of electronics?" :-)
regards
john

I would think you want a 'stright line frequency' where the capacitance
changes as the square of the rotation. IE: at half open position the
capacitance is down to 1/4 of the value available at full mesh.

I have a few of those ARC-5 tx caps in my junk box, and at least one
with the dial drive. It binds just a bit though as if the drive shaft
is slightly bent. Just enough to be noticed while turning it with a
good sized knob attached.

With a good 'roofing' filter ahead of the final mixer you should be able to knock down the images from the 1.7mhz if before reaching the 85khz one. I have three 1.7mhz double tuned cans available, with all three in series top coupled with gimick caps I should be able to achieve enough selectivity to avoid secondary image problems. The use of a 455khz IF is also a good idea, and I have a few Collins mech. filters that could be used there as well (a 2.0khz bw out of an R390, a 2.7khz that looks like an S line filter, and a large unit of 1.8khz bw that came out of an if adaptor for an HRO-50 or 60).

With proper layout and shielding I don't see a problem using the 6AR11 in the two stage IF. Hell, they were designed for use at 47mhz in a dual stage TV if where cross coupling would be even more of a problem! The 6AR11 is an excellent semi-remote cutoff amplifier with good overload and cross mod specs equal to the pentodes used in the HBR.

As for a new design with todays parts, well I have several ideas here begging to be tried. I have quite a few 'Samples' from Analog Devices including many DDS chips. The 400mhz DDS parts would make a great HFO for a single conversion receiver with an IF at 9mhz (again more junkbox filters, including about 1/2 dozen 9mhz 3.2khz 8 pole units out of Gonset Sidewinder rigs purchased at Dayton years ago). Thought I'd use three IF stages with a filter between EACH stage and a final one before the detector. Probably use MC1350's or ancient CA3028's as the IF amps. The front end would use a quad DFET (Siliconix) switching mixer that was in the handbook for several years driven at twice the required HFO frequency (to get push-pull drive using a D Flipflop). Bowing to the junkbox, the front end would be a double or triple tuned filter using

toriods bandswitched using a standard coil tuner chassis as the switch. (The toriods fit nicely in the tuner strips). An 8051 series micro drives the DDS, frequency display on 7 segment LEDs (I have enough of these to choke an alligator) and a rotary encoder drives the micro to select frequency.

Maybe I'm crazy, but I still wonder about puting in a second conversion down to 85khz to use those ARC5 IF cans! Anything wrong with a hybrid radio using the latest IC's and microprocessors along with 60's compactrons! (Just what kind of bandwidth will a properly aligned 85khz if strip using arc5 cans give?)

The above radio would probably end up being a transceiver (cause the extra circuity isn't much) but the finals would end up being 1 or 2 1625 bottles 'cause I have at least a dozen of 'em in the junk box. (Also some IRF531 mosfets which might make a good linear final for about 25 watts a pair....though maybe not to 30mhz....).

I've rambled enough....

Indeed!

2572. Re: QUESTION: Homebrew Spread spectrum

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-03-31 02:24:27 UTC
From: Jim Pennell <Nospam@killspam.com>
Message-ID: <vZpac.8196$Dv2.5624@newsread2.news.pas.earthlink.net>
Source record: 27259

A company I used to work for manufactured a frequency hopper spread spectrum unit.

It was a 'slow' hopper, with Ack/noack for packets so it would retransmit a missed data packet which covered the case when a particular channel was occupied.

The acquisition method would also work for a pretty fast frequency hopper too. It used a master unit that sent a sync signal burst every time it jumped to a new channel. The remote that was looking for the master would jump in a duplicate pattern, but at a slower jump rate until it heard the sync signal from the master. the remote would then start hopping at the correct rate, and follow the master as it hopped.

Acquisition might be a bit slow, but it did work nicely, and it allowed other remotes to be turned on at any time and acquire the network.

==========

I have never tinkered with an amateur radio version, but it seems to me that the ARRL has a book on spread spectrum and there are some FCC mandated requirements for the PN code, or the hopping pattern for freq hoppers, to allow the FCC to be able to listen in.

The FCC also limited which frequency ranges Spread Spectrum can be used on, so I'd do a bit of digging before trying to build hardware......

I have a circuit that puts out 0 - 5 volts to drive a meter. However the meter I want to use accepts 0 - 10 volts. The response is linear, so if I could just double the voltage, I could make this work. Any simple devices or circuit that can accomplish this? Thanks, Scott.

How to synchronize to direct-sequence spread spectrum
should be obvious (think Costas Loop).

A sliding-window correlator is a common approach, other-
wise. Three correlators in parallel. One runs a little
ahead, one is on time, the third runs a little behind.
The LO free-runs (deliberately) a little slow or fast.
When the locally-generated PN sequence lines up with
the received sequence, the outputs from the early/late
correlators track the LO, while the on-time correlator
provides the output.

Look in back issues of Wireless World from 1993 for a
fully worked-out example.

That only works with a tuning range of about 2:1. The type of ham band
rx being described has a much more limited tuning range, and needs an
almost-linear capacitance curve to get a linear dial.

Not really. The TV applications were broadband and low gain compared
to what you're trying to do at HF. And the manufacturers could do a
whole bunch of not-obvious tricks and PC board prototypes to get what
they wanted.

> The 6AR11 is an excellent semi-remote cutoff amplifier with good
> overload and cross mod specs equal to the pentodes used in the HBR.

I agree 100% - it's just that cascading them at 85 kHz may prove
troublesome.

OTOH, in a 455 kHz design where the selectivity comes from the xtal
filters, you may be OK.

> > Some alternatives to consider:

> Gonset Sidewinder rigs purchased at Dayton years ago).

The big question with DDS is the spectral purity of the output. Even
weak artifacts can cause all kinds of birdies and other troubles in
today's RF environment. This is one reason so many folks find the old
designs so appealing - they are "clean" except for the obvious things
like images.

> Thought I'd use
> three IF stages with a filter between EACH stage and a final one before
> the detector.

Very good idea. The best filter goes first, then "cleanup" filters.

> if strip using arc5 cans give?)

The original design gave a decent SSB passband if the rods were pulled
up. But the shape factor isn't the best and the selectivity winds up
so far from the antenna....

> The above radio would probably end up being a transceiver (cause the
> extra circuity isn't much) but the finals would end up being 1 or 2 1625
> bottles 'cause I have at least a dozen of 'em in the junk box.

Great bottles but the sockets are a pain. Unless you hack up an ARC-5
tx.

The biggest headache I've encountered in transceiver design is finding
a heterodyne combination that works in both directions and uses

available components. All of the classic ones are compromises in one way or another, either on rx or tx.

Dear all
I want to design a DDS board which has attenuators on the output to provide a low level output (<-100dBm)
I have a venerable HP8640B which can give a calibrated output to -137dBm
To achieve this HP have gone to extraordinary lengths to shield the oscillator attenuator/output amp circuits and any control lines - I note there are at least two stages of bypassing/low pass filtering with an intermediate shielded section

My question is: how do I get data and power lines into my DDS chip (in a shielded enclosure) and prevent RF leakage out which will limit the useful minimum level out from the DDS board?
I presume I will have to use a buffer of some sort for the data lines and extensive bypassing on the power lines. I want reasoanbly quick update speeds for my DDS, which is a serial port, which will mean data rates in the MHz region.

Thanks

Richard

Richard,

I don't have direct experience about this but I'm developping a VNA with pretty tight specs so I had to think about things like this.

Here are some of my reflexions, and also some ideas provided by other people :

Low output level is not the same thing as low leakages : it depends on where leakages couples.
What you don't want is leakages coupled to the output port, but you may have some leakages that will be stopped by your main enclosure (OK, not mW though) and still maintain low level at the output port. Whether this can be tolerated or not depends on the rest of your equipment.

Besides the DC/command lines, to achieve accurate low level output will require good internal shielding between the DDS section and the attenuator : 1dB accuracy at -100dBm means leakages coupled to the output has to be under -120dBm and 0.1dB lower this to -140dBm.
At this level, ground plane management can be "difficult". Depending on your frequency range it might also help to provide separation between the DDS and the attenuator with a small xformer.
You'll have to think to current paths for both cases, high frequency and low frequency, if your frequency span doesn't allow an xformer, because currents

spreads differently, depending on freq.
I've used fasthenry (a freeware prog) with great success to model this kind of things in another application.

If you really need very, very good shielding (radiated power inside the enclosure) it might be easier/better to "double shield" the beast and to add a lowpass section between the 2 shields.
Again, think to current paths and that common mode is your enemy ("ground" potential that's shifted by return currents).

For the DDS command lines, optos might help, but maybe not as much as expected if you want a high speed link.
If you really want high speed and isolation I'd go for an optic fiber. Not very expensive and coupled with a double shielded box, you'll have vanishingly low leakages.

Just think to neglect nothing and you're OK.

Thanks,
Fred.

Electrically yes. I'm not sure if a scope can be configured to act like
a station monitor, so you may not be happy with what you see.

A different meter. Sorry, I couldn't resist.

If you have a 12V supply handy you could use an op-amp to amplify the
0-5V by 2. You'd need one op-amp, a bypass cap or two, and two
equal-value resistors. This is an easy circuit and should be in any
ARRL Handbook after 1970 or so. Even one of those "Engineers
Mini-Notebooks" from Rat-Shack should do, if there's one on op-amps.

An easy way to double the voltage is to use an op amp circuit. If you use an op amp with rail-to-rail input and output, or at least including the negative rail, you can get by with a single power supply. You'd just feed power to the op amp (e.g., 12V or 15V to the +power pin, and ground/common to the -power pin), connect the input signal to the (+) op amp input, and connect two equal-value resistors (say 100kohms each), one from ground/common to the (-) input, and one from (-) input to output. Meter to output terminal. To find an appropriate op amp, try searches on web sites like National Semiconductor, Maxim, Analog Devices, Texas Instruments, Linear Technology, ... You get the picture...a awful lot of companies make such parts. Just pick one that suits your needs rail-to-rail operation and power supply voltage...likely everything else will be OK...stay with low speed ones for low power and lack of problems with circuit layout.

But why not make it even simpler? Take the meter apart, and locate the series resistor. Replace it with a resistor of half the value. Then you'll have a 0-5V meter, and no power-draining op amp circuit will be required.

Cheers,
Tom

I started to post an answer like that, until I realized that he
didn't specify what kind of meter.

I'd even go further, to point out that while analog meters have
all kinds of scales, they may not even have a resistor built in.
They might just be a current meter and expect an external resistor
in order to read whatever is on the scale. This the more so
if it's just the movement, but obviously not the case if it's an
actual "voltmeter" with the movement in a box etc.

If it's just the meter movement, and does not actually have the
resistor inside, then one has to calculate the resistor value
using ohms law.

Open up the meter movement and locate the resistor that is in series
with the meter movement. Using Ohm's Law, calculate what the correct
value is to make the meter's pointer indicate full-scale-deflection
with a 5V EMF applied.

Fred gave you a very nice bunch of ideas.

For data lines, you might consider using differential signalling. You can apply common-mode choking fairly easily, without disturbing the data. But if you put capacitance to ground, you'd have to be very careful to keep it balanced, and to not have so much it causes signal degradation.

We fairly regularly deal with high isolation out to 100MHz and a bit beyond, and it hasn't proven to be terribly difficult. We have things like switching power supplies, whose noise would cause lots of problems if it got into the wrong places. One of the key tricks is to keep loop areas very tight. Another is to be very sure that there is a return path for everything, and that the return path is close to the outgoing path. That's really the same as keeping loop areas low. There is a lot of advantage to using multilayer boards and SMT parts.

Not long ago, I revamped a board that had a heavy cast shield "clam shell" bolted around a critical area of the board. (It digitizes wideband analog inputs, and has lots of digital communications going on not far from the analog stuff.) My new design uses a simple snap-on folded metal shield, and I'm not even convinced it needs that...and the spuriouses are at least 20dB lower than the old board, down in the -120dBfs region as I recall. In laying out the board, we simply paid a lot of attention to keeping things very tight, taking advantage of SMT parts and differential signalling. Think of everything as an antenna that can radiate and/or pick up signals, and minimize their ability to do that. And realize that current in any copper conductor causes a voltage drop that you must avoid sharing with some other circuit you don't want the signal getting into.

I gather you want a stepped attenuator on the output of your DDS. You may well want to have the attenuator itself be a separate board with some decent shielding between sections, and essentially DC controls (to relays??) to control the steps. Common mode choking on the RF signal cable should be helpful.

Cheers,
Tom

What's with the personal abuse? Her answer made perfect
sense to me.

A direct sequence signal is spread by BPSK modulation at the
chip rate. Double the frequency and the 0/180 phase shifts
become 0/360, removing the spreading.

Have a look at the ADuM1400 series of magnetic isolators from AD.
Yes, double shielding might be necessary and probably differential
signals. Put the whole into a solid block of Alu.
What attenuator are you going to use ? For what frequency range ?

The relay contacts can handle it fine, provided you
don't hot switch. You will introduce an impedance
bump in the transmission line. (The relay contacts and
associated wiring become part of the transmission line.)
Don't know how large that will be.

25 of us work in a metal building and only receive 1 clear station. I have a great outdoor antenna. I could get a cable boost system and run coax to everyone's radios, but I would like to instead boost it up to 100 mW or so and run it into an indoor antenna.

I have found amps that do this to boost cable signals for splitting, but I cannot find one a little more powerful to feed an antenna.

Any ideas?

Program models a 1/4-wave vertical and 1/2-wave dipole antenna to
demonstrate how input impedance and SWR behave in the vicinity of resonance.

Transmission line Zo can be varied to match the resonant antenna. Frequency
can then be varied to observe how SWR varies over the band.

Download program R_X_SWR in a few seconds and run immediately.

No increase in price.

When I was very poor, I built a spectrum analyser. It took an eternity,
albeit much was learnt. By far the costliest and most time consuming lesson
was finding I hadn't a hope in hell of meeting a decent performance without
enclosing every circuit block in it's own screened casing, each with
extensive 'cleaning' of the incoming power and control lines. Even the power
supply transformer had a mu-metal screen to reduce magnetic field effects.

Another neat thing: message ends ("SK" or "VA" run
together) can be, and sometimes is, spoken as
"diddleedadeda" - pronounced diddle e dah de dah
and that has a certain "ring" to ir.

The big problem with DDS is getting a good anti-aliasing filter on the
output to satisfy Mr. Nyquist. Trying to build a good 'brick wall' low
pass filter is insane. Running the DDS with a clock many times greater
than the highest output frequency helps, with an injection frequency of
39mhz on 10 meters with a 9mhz if a 400mhz DDS clock is 5x the Nyquist
requirement. Rather than using a low pass filter, I'd use switchable
bandpass filters, much more rejection of unwanted spurs and a cleaner
output. Not as simple to build, you have to switch filters to change
bands, but hey, I can always GANG several tv tuner chassis for my
band switch! (I knew those old TV sets I caniblized would come in handy!)

>
>>Thought I'd use

Actually those filters are identical. But another idea is a double
conversion with both 9mhz and 455khz if's. Then by tuning the second
conversion oscillator you can 'overlap' the bandpass of both sets of
filters to use only a portion of them, and if you also move the bfo
frequency you can move the position of the signal within the resulting
bandpass.

>

>
> Great bottles but the sockets are a pain. Unless you hack up an ARC-5
> tx.
My junk box has a few 1625 size sockets, two ceramic 'plate' types and a
large saddle mount. Actually these sockets are easy to find and not too
expensive. Antique Electronic Supply has them, and they show up on Ebay
often. No need to use ones out of ARC5 xmtrs.

I also have a good number of 6AG7 tubes, they would make a good driver stage for the 1625s. (BTW 6AG7 is sorta an octal version of the 6CL6). If I used a single 1625 in the final, it would be good for about 25 watts output without straining. Then if I needed more power, I'd build a linear amp using a 2 or 3 811A's (that's 340-410 Watts PEP output). Not a full gallon, but the extra few db ain't worth the cost! I have some 813's in the junkbox, but the sockets for them are costly, and they have such HIGH output capacitance that making a good tank circuit in a single ended amp is rather a pain. Still a grounded grid tetrode circuit looks interresting! (cathode driven with normal g1 and g2 voltages).

>
> The biggest headache I've encountered in transceiver design is finding
> a heterodyne combination that works in both directions and uses
> available components. All of the classic ones are compromises in one
> way or another, either on rx or tx.
If you have enough filters you can put separate filters in the tx and rx chains, and even use double conversion on the rx but single conversion on tx. Then you can use a separate tunable bfo for the receiver. The bandwidth and center frequency of the tx filter can be selected for good audio, while the rx filter(s) for selectivity. Tx bandwidth is a function of audio channel filtering, alc, and NOT overdriving anything.

Many newer eletrolytic caps have both a 'surge' and a 'working' voltage rating. I don't know if this is just a new parameter, or if the newer caps were engineered to handle a brief surge of voltage while 'charging'. In anycase using 150v caps in a circuit supplied by 120v is NOT allowing for the peak voltage. I think in a half wave circuit there is probably a lower peak since it is reached in double the time between peaks. Even so, 180v or even 200v caps should be used. I've seen filter caps now being made in a 160v rating for line service, but that's still too low for safety (but maybe these units carry a higher 'surge' voltage rating).

Hi Jack,
it wasnt meant as abuse - merely that I didnt understand Lauras
references. If you think being called a smarty pants is abuse, then
you have had a VERY sheltered life - or perhaps its cultural, - BTW -
I went to her site and read the papers she has there - the writing is
clear, succinct and on a level that I can understand. Maybe it was
asking a bit much for Laura to "dumb down" her reply, and I have no
right to expect her to do this. But I rely on these groups as
tutorials on the wide variety of things I dont understand - I am a
mere technician who spends his working life trying to figure out what
the design engineer was trying to do and why it failed after only a
few months in service.

Hope this clears this up

Robert,

First the legal issue...

For an unlicensed (FCC Part 15) transmitter on
the FM broadcast band, your field strength from
your transmitter must be less than 250 microvolts
per meter measured at 3 meters from the antenna.
This works out to a transmitter power measured in
NANOWATTS [about 6E-9 watts for a quarter wave
vertical antenna if my memory serves]. This is
about 10 million times lower power than the 100
milliwatts you were thinking. Basically this
gives a range with a sensitive receiver of at
most 200 feet with a clear path and no
obstructions.

Secondly, the practical issue...

These cable amplifiers have a high noise figure
and they produce lots of intermodulation
distortion. They are designed for relatively
high input levels and with the high noise figure,
they do not work well with the weak signals from
an antenna. A friend tried one of these once to
see if he could boost his outdoor TV antenna
signal. It made matters worse on most of the
stations.

Maybe a passive antenna would work: the sort of thing that has been used to get cellphone signals in and out of buildings that otherwise are dead areas. In its simplest form, for broadcast FM, it could be just a 56" piece of wire hanging from the center conductor of the coax that you bring in from the outside antenna; no amplifier involved. I've used this scheme to get out of the basement with 1 watt on 2 meters.

Congratulations!

I still have my original Ameco AC-1 15-Watt CW transmitter, completely intact with all original parts and accessories, all in perfect like-new condition, and a copy of the whole manual. If you want me to look at or measure anything for you (e.g. the coil you mentioned?), just let me know. I am at tomg AT fullnet.com .

By the way, I think that I paid $14.98 for the Ameco AC-1 kit, new, back in about 1969. I built it, tested it, and then never used it. And I HAVE had people offer me hundreds of dollars for it, "out of the blue", several times over the last few years. There's a picture of it on my webpage (see URL, below).

Good luck!

Regards,

Tom Gootee

2610. Curve Tracer: UPDATE

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-01 15:50:37 UTC
From: tomg@fullnet.com
Message-ID: <11915d6.0404010750.55b4c398@posting.google.com>
Source record: 27197

[Sorry for the "commercial" instrusion, if you're not interested.]

Curve Tracer: UPDATE

My CURVE TRACER webpage has been updated:

For details, cool photos, etc., see:

http://www.fullnet.com/u/tomg/gooteect.htm

With the kit version, I now (again) supply ready-to-use printed circuit boards (PCB's), etched and drilled, and "silk-screened" on the component sides. (And I still offer the lower-cost version of the kit, with the "do-it-yourself" PCBs and *everything* needed to easily make them.)

The Curve Tracer now also includes a complete set of circuit SCHEMATICS (along with the component-layout and wiring diagrams, parts lists, instructions, etc, which were always included).

Also included, now, are diagrams with TEST-POINTS' waveforms, DC voltages, and resistances.

A complete "Operator's and Service Manual" is also being created (which will automatically be supplied to all past purchasers). My goal is to make the manual as good as the older Tektronix ops/service manuals! It will be produced in both bound, paper form and in electronic form.

I now also offer a "fully-assembled and tested" version of the Curve Tracer!

I have been getting some wonderful feedback from Gootee Curve Tracer users. So check it out, at:

http://www.fullnet.com/u/tomg/gooteect.htm

Thanks!

Regards,

Tom Gootee

Hi all..
I have a couple of T200 cores laying around that I want to wind with No 14 enameled wire.
Can anyone give me a ballpark figure how many turns I will need to wind them to add inductance to the ends of my 275 watt Johnson Matchbox for use on 160 meters?
thanks in advance de Denton WB7TDG

What attenuator are you using ?
-100dBm is a lot of attenuation.

Seems like email ports everywhere are having troubles these days.
It's a sad state of affairs that there is so much spam. I rather like
the idea of being able to charge people (spammers especially, of
course) a nominal fee for me to open their email. That would cut down
on the spam a lot. Anyway, trying another route to get to Fred, and
sorry he had to use a public forum to page me.

Cheers,
Tom

>that's still too low for safety (but maybe these units carry a higher
>'surge' voltage rating).

Peak voltage reached is the same whether a rectifier is half-wave
or three-phase full wave. It is dependent on the AC input voltage.

Surge currents are serious concerns in semiconductor diode
rectifier circuits. Not just within the circuit but from the AC line
itself. To get really worried, dual-trace scope the AC input line
with second trace on the diode DC output, sync on the AC line
set to trigger a sweep above the normal AC peak voltage. Watch
during a time when other appliances in the house are working,
like food mixers and bread machines. Might be surprising...

For details of the guts of capacitors, the Cornell-Dubilier website
used to be good. Surge ratings depend on the foil, the electroyte,
size of the lead wires. Lots more different things for tantalums.
There's not much one can do if someone else makes them, just
read the specs and hope for the best.

For hobby work of onsies and twosies, if in doubt use the higher
working voltage ratings. That way there's less time wasted on
analyzing all the busted parts after being too economical.
Hobbyists don't have all the time in the world to shave designs
down to the nubbin to save pennies per unit on a thousand-lot
production run.

Got me John,
So how to get -99dBm, considering the DDS outputs in the
order of 0dBm.
Are there any decent digital step attenuators around ?
The better switches available at minicircuits have an isolation
of 80dB when off, their analog Attenuator has a range of 55dB.
In 2 stages then ?

I thought I would use switched sections with various sections switched
by relays - each section shielded if necessary.
The DDS will give an output down to -50dBm or so under software control,
though spurious outputs are not necessarily attenuated by the same
amount, so it is probably not a good idea to use the full attenuation range
My board will be double sided unless I *need* to use a more expensive board

A good scrounger approach if you can find tuners with good contacts!

Here's another approach, shamelessly copied from Elecraft: Bandswitch
the low-level circuits with small latching relays and some logic
circuitry (a PIC or TTL can easily do the job). These relays are
available from Digi-Key - Omron is one mfr. - and are not too
expensive in quantity.

Agreed. The ARC-5 ones are good for submounting, though.

Oh yes, used them in several rigs.

> watts output without straining. Then if I needed more power, I'd build
> a linear amp using a 2 or 3 811A's (that's 340-410 Watts PEP output).

But will 25 watts drive a two- or three-hole 811A amp in grounded
grid? All of the data I've seen says you need about 15 watts per 811A
in GG. Grid Driven requires a lot less (about 5W) but then you need a
grid tank, etc.

> Not a full gallon, but the extra few db ain't worth the cost! I have

I always thought the big advantage of GG was elimination of the need
for screen and bias supplies.

Sure, but by that time you're actually building a separate transmitter
and receiver that share a VFO and not much else.

> Then you can use a separate tunable bfo for the receiver. The
> bandwidth and center frequency of the tx filter can be selected for good
> audio, while the rx filter(s) for selectivity. Tx bandwidth is a
> function of audio channel filtering, alc, and NOT overdriving anything.

Agreed!

But since I'm primarily a CW op, the problem is greatly simplified in some ways. My current homebrew transceiver uses a different het scheme for tx and rx, sharing a common VFO. Both paths are single conversion. Requires that the het xtals be dead-on freq (handled by trimmers across each xtal).

I'm on a similar project and had a look at these issues.
Depending on the frequency and the relay, the isolation of an
off contact can be as low as 25dB. I assume you'd plan on changers
(SPDT) with the idle on 50 Ohms. The relay attenuator sure uses
a lot of board state.
The minicircuits variable attenuator unfortunately doesn't go to DC,
and while spec'ed to 10MHz, I didn't measure the lower border myself
yet. The minicircuits step attenuator have no steps greater than 20dB
and are rather pricey. They also have a lower border of 10MHz.

I'm also not yet sure how to get rid of the digital noise, especially
when using high update rates. I'm considering an FPGA to have the
lowest possible digital clock frequency for the amount of operations.

This company is selling them for a paltry $425.00 used.

http://www.tubesontheweb.com/TU06.HTM

It is also known as a type 5680. For the $425.00 you will get when you find
a buyer, you can buy an old ARRL Handbook and look up the specs.

Meanwhile, scroll down to the bottom of

http://wordindex.sourceforge.net/testdata/usenet.col-20000829-1152/094-135.col

where it says "A pulse triode used in radar modulators and similar
applications. Used to switch a very high voltage (20-30 kV) and moderate
currents (tens of amps)at a low duty cycle. Used to drive a magnetron.

"These kind of tubes are often poor performers as modern ham amp tubes, as
they are usually quite non-linear. They might be better suited to class
Camplifiers. I have heard that this type of tube is very good for a tesla
coil driver, if you are into that sorta stuff."

Google is your friend.

Source record: 27218

Only now do I have a chance to react to some of the suggestions...

I guess one poster here is right, I will just have to fiddle a bit more with the pi network (since at the B+ voltages suggested here my plate current would be way high) and I will have to live with the chirp. Nobody has complained yet anyways and maybe the chirp is worse in my receiver than on the air, as someone here suggested. By the way I use a Icom R75 for a receiver and switch the antenna off during transmit-still plenty of a signal seems to get into the receiver anyways.

By the way, I see suggestions how to just "stretch" crystal controlled oscillators a bit by adding a suitable coil and capacitor in series with the crystal. Has anybody tried that with the AC-1??
Would be nice to be able to get out of the ways of some of the big power guys.
Any suggestion would be welcome.

Uwe

2632. Transistorized "cascode" RF amp?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-02 23:03:42 UTC

Back from good old tube days, cascoded triode RF preamps were good for high gain, stability and low noise.

Anything out there in transistorised version, or there is there better stuff available? Looking mainly for preamps on HF to be used with low gain antennas, like small loops or beverages.

An rf choke or variable inductor of between 7 and 20 uH in series with a variable cap of about 200 pF in series with a crystal, will pull the frequency. It's called a variable crystal oscillator or VXO. You're probably using FT-243 crystals, though, and they don't pull very far.

I have to say this again: Time to put this thing on the shelf. For the time and trouble you are putting into it you could build a solid-state rig that would put out as much power, have a VFO and not contain life-threatening voltages.

Back in the 'good old tube days' it was difficult to get below a NF of 3 db on 2 meters. Now it is easy to get way below that with a good FET. For HF almost any RF device now will take you very low in NF with good gain.

There are versions of the cascode that use FETs for HF and above.

You definitely saw them in the early days. The one that comes immediately to mind was a cheap preamp described in Ham Radio in the early seventies, and was available as a cheap kit from Hamtronics.

I think there were some shown with bipolars, but I can't dredge up any specific memories at the moment.

It was obviously a transitional thing, since you're right, one doesn't see solid state cascodes very often. I have no idea if they were used decades ago because it worked around limitations of early solid state devices, or if it just seemed to be the thing to do since they had been common in tube circuits.

The author of that Ham Radio article (actually, there were two, and he used cascode FET amplifiers in various projects described later), I think his name was Jerry Voigt, had grumlbed about the then relatively new dual-gate MOSFETs, but in a followup letter he admitted than a dual-gate MOSFET was basically a cascode device.

If there was an advantage to be using cascode circuits today, then you'd be seeing them.

A lot has changed. Bipolars came in, and they couldn't handle strong signals well. The JFET came along, and it was seen as the device to use for best performance. The MOSFET came along, and again there was a switch. Sort of simultaneously with MOSFETs, but not really adopted till later, bipolars started being capable of low noise and strong signal handling. MOSFETs are now rare for receiving applications. Gasfets came along and they seem to be be the thing for low noise RF amplification.

Thank you Paul, since I have a crystal socket on the front of the little box
it ought to relatively simple to try out this scheme and see if I can't get
a "range" out of this one frequency device.
And yes you are right, I have a few FT 243 but others are on order.

It is my experience that whatever I do around the crystal it stops it from
oscillating but I will try your suggestion nevertheless.

As to high voltages I grew up in Europe where I got used to (and sometimes
shocked by) 220V and now I can't let go ...

Paul, your concern for a new ham is very much appreciated, but ever since I
wanted to be a ham I wanted to know code and I wanted to build my own gear,
preferably tube gear.
It gets cold in Maine and these at least warm your hands in between QSO's.

I will probably never own an SSB or a phone radio and as somebody mentioned here, for communication we have other solutions. For me being a new ham opens a world of learning and tinkering possibilities with the side effect of being able to communicate with others via code.

And I think I can learn a whole lot by working on this transmitter. And I will need all the learning I can get because someone mentioned a different, slightly more sophisticated tube transmitter using two 807's in the final. I would love to build that and appreciate more info on the device.

And Paul, lest you get the impression I hate silicon, I just finished a Rockmite-very cute.

Thanks again and keep the advice and help coming.

Greetings from Maine

Uwe

> grid tank, etc.
>
The 15 watt figure is close, I think the offical handbook rating was 12
watts per tube in GG. The higher figure was with an UNTUNED input
without any impedance matching network (just the way most 811 gg amps
were built, since the average exciter provided about 100 watts output
who cared?).

TWO 811A's should easily be driven by a 25w out exciter with a good
matching network between the amp and the exciter, it might be pushing it
to drive three (But you can get 35w pep out of a single 1625, or use two
of them in the final for 50w output in AB1).

BTW the 1625 used to be the last cheap final left. Fair Radio had new
ones for $4.50 up till last year. Now they only have used ones left for
$3.00. Everyone has discovered that 6159's are really 25v heater 6146's
and the price has jumped from a few bucks to the $18 range. The US made
811A's are drying up (and you have to be carefull of those Chinese
tubes, some are OK, others don't last long). I remember back in the
60's when BA was selling NOS surplus 1625's for $0.25 each! (Should
have bought several gross and put them in storage, but not on a
teenagers budget).

> >
>
The 813 isn't such a great tube in pure GG. Most of the spec's I've
seen show it as only 200 watts or so output in GG. Problem is the tube

just doesn't have much power gain in GG. If you bias it as a tetrode the power gain goes way up, you can still run it 'cathode driven' to avoid neutralization though.

There are two ways of looking at cascade, the devices are in series for
dc and ac, or only ac. The above link shows the latter. I had an idea
for a hybrid cascade amp of the first kind. The input would be a jfet
which sorta becomes the emitter resistor for a bipolar transistor as the
second stage of the cascade amp. The bipolar is run in grounded base
(for ac, normal bias network and base bypassed to ground with a cap).
Would give the advantages of high input impedance of the fet and high
gain from the bipolar.

It's been done. There was an article in Ham Radio magazine in 1970 or
1971 about a six meter converter. Just as you described, a common source
JFET with a bipolar transistor as the upper element. Used a Vackar oscillator
to make it tuneable. It might be this one:
Six-meter converter, improved K1BQT 50 Aug 70
The date is about when I remember it, though I don't remember K1BQT being
the author.

Sure, there are _op-amps_ that have cascode input stages. There are
bootstrapped cascode input stages used in feedback amplifiers that
have extremely low input capacitance and very low distortion when
driven from high source impedances. One of the FM tuner manufacturers
long ago used a cascode input stage. With transistor amps, you can
run the input transistor at low voltage and therefore low dissipation,
and have the output transistor capable of large swings, and thus get
good dynamic range. I don't know that there's any particular noise
advantage, per se. But it does let you pick the best transistor for
each part. Another variation with transistors is a "folded cascode"
where the input transistor is one polarity (e.g. NPN) and the output
one is the opposite polarity (PNP).

Cheers,
Tom

Hallo again.

This is specialy for Eddy and Dave

I just finish the building and testing of my 4CX5000 final.
Buy the way....I build the Broadcast Electronics version.
Today i tested the amp with an driving power of 150 Watts and the
output power was 8000 Watts. It ran it on 7000 volts and it consume
about 1.8 amp.
I alsow find out that the tube is not a 4CX5000A but a 4CX5000J/8909.
I measure the filament current so thats wy the 10.000 watts is not in
reach.
The difference between these tube's is the maximum frequency range.
The 5000A runs till 220 mhz and it's brother...the5000J runs till 100
mhz.
But still i feel pretty good about this project.
If You wanna see a picture of this final amp just mail me and i will
send You one.
Thanks for supporting me.

Greetings from Holland.....Onno

Agreed 100%. Note, however, that the driving power figures in the books are
usually theoretical, derived from tube characteristics. Usually, there's no
provision made for losses in matching circuits, etc.
>
>TWO 811A's should easily be driven by a 25w out exciter with a good

Again, note that those output figures don't include circuit losses.

But in general I think you'd be OK with a single 1625 driving up to a pair if
811s if the matching circuits are lowloss.
>
>BTW the 1625 used to be the last cheap final left. Fair Radio had new

I've got a bunch of used and a bunch of new. Also a big pile of 807s, which
have been my homebrew final of choice for quite some time now.

Here's a hint: Look at the 6BG6-G sweep tube. They are still very common (the
GA's are liked by some audiophiles but the Gs aren't) and their ratings are
very similar to the 807/1625. Looking at their construction, one wonders if the
6BG6-G isn't just an 807 with an octal base.

>Everyone has discovered that 6159's are really 25v heater 6146's

Yup.

What about the Russian 811s?

>I remember back in the
>60's when BA was selling NOS surplus 1625's for $0.25 each! (Should
>have bought several gross and put them in storage, but not on a

Same here. The lowest I ever saw them was 19 cents in quantity (I think the quantity was 100). And of course there was a pair of them in every ARC-5 tx, which could be had for a few dollars from Fair Radio.
>>

The B&W L-1000 amp used a pair of 813s in GG, as I recall. How did they get 'em to work?

>If you bias it as a tetrode
>the power gain goes way up, you can still run it 'cathode driven' to
>avoid neutralization though.

Makes sense, but the other problems (socket, filament voltage, high C, need for higher plate volts to get full power) make it a second choice compared to, say, a pair of 811As. (A pair of 811As needs only 1500 V to do 450 W input, while a single 813 wants more like 2500 V)

Source record: 27239

Magnet wire is a generic term for wire intended for winding coils, with very thin insulation so as not to waste precious winding space.

Enameled wire is simply one form of it, probably the most popular. Enamel is a lot thinner insulation than a plastic sheath so won't waste winding space.

In the old days there were enameled, single cotton covered (SCC), double cotton covered (DCC), single silk covered, and some others. Today enamel is used as well as various plastics. One popular type melts away with a soldering iron, making stripping the end unnecessary, very convenient.

They are all magnet wire.

Paul, how interesting, I just had Wes Haywards book in hand the other day at a local hamfest. I own the Solid State Design Book and had considered Radio Frequency Design but found that one rather technical. But "Experimental Methods in RF Design" caught my eye but also caught me at the end of the day without the necessary $50 to take it home.

Experimenting is really what all this is about for me and I do lack some of the foundations and tools for successful RF tinkering, so I always look for a good introduction.

And somehow tubes, which seem to deal with electrons on a macroscopic, nearly mechanical level seem to be a bit more accessible than transistors which I think deal with all this on an atomic level.

And here you send me a link to Haywards website. Well thanks, and yes, nice mountains.

I went and added a choke and a capacitor to my crystal and believe it or not it actually still oscillated. I did some measurements and found that I can pull the crystal (I used one of the crystals out of the rockmite!) from 7038 to 7040, after being rockbound that feels like now I am "all over the place". And while I was fiddeling with the radio I heard a station and ran my first QSO on a frequency I couldn't get to until 3 hours ago, with rigged up parts and clip leads all over the place!! Radio work at its finest.

But one solution immediately leads to the next problem, how do I know where I am. What do they call them, frequency counters???

Regards Uwe

<< wonder what is the difference between enam. cu wire and magnet wire >>

Jan-Martin-

To the best of my knowlege, the only difference is that you could use other kinds of insulation on wire to be used for magnets. In other words, enameled copper wire is one type of magnet wire. Other insulating materials such as cloth, fiberglass and asbestos have been used.

I got started in electronics by tearing up discarded radios for their parts. Radios from the 1930s and 1940s had speakers that used an electromagnet instead of the permanent magnet used in most of today's speakers. In additon to providing the speaker's magnetic field, the electromagnet acted as a filter choke inductor for the radio's power supply. Those old speakers were a good source of enameled copper wire.

Yes, I'm resisting spending the money, too. I can buy a lotta parts with 50
bucks.

> And somehow tubes, which seem to deal with electrons on a macroscopic,
> nearly mechanical level seem to be a bit more accessible than transistors
> which I think deal with all this on an atomic level.

Electrons don't know where they are, tube or semiconductor, it's all the
same to them. Study the intro chapters in the Handbook and SSD and do some
experiments and it wil start to make sense.

> But one solution immediately leads to the next problem, how do I know
where
> I am. What do they call them, frequency counters???

Uwe, if you don't know where you are, you are asking on the wrong newsgroup.
:>

If you're only moving 2 kHz and you're well inside the band, it really
doesn't matter. You have a digital display on your receiver, so you should
be able to kluge something together that will let you zero beat the other
station.

Be careful with those little crystals. They won't take a lot of current,
not as much as one in an FT-243 holder. You could pop it. You'll hear it
click when it blows. Why not build a VFO from SSD?

Thanks for pointers, I will have look at references mentioned.
Another requirement would be good handling strong signals, like using 807 :-)

I am trying to build the converter with strong signal handling capabilities,
low noise and high gain.

Next step is looking at the mixers and low noise synthesizers.

Thanks a bunch!

So you turned it into a Heathkit!
Did you every try to put it back together?

I used to find old AA5's in the trash and gut them for the parts.
I later built a brand new one using the best of the parts from
the dead ones. So I guess that was my 'Frankenstein' radio.
The chassis was a frame from an old radio that had held a pc
board. I just slipped a piece of galvanized steel where the pc
card had been and then drilled and punched it out for my chassis.
It was actually a very good radio, and doubled as an amplifier for
a photograph turntable (also found in the trash).

You are working at it wht wrong way. The three things you mentioned do not go together. What you want is somthting with strong signal handling and low noise. You use just enough gain to override the mixer noise. Then make up the gain at the IF stages after the filters.

Or, no rf stage at all.

I can't remember what frequency this if for, if it was mentioned.
An RF stage is only needed if there is need, like one needs front
end selectivity to eliminate images or to keep the mixer from overloading,
and the amplification is there to overcome the losses of the filter.
Another need would be that a good low noise stage is needed because
what comes later is too noisy.

Well, I've only done the first two. I was just trying to persuade him to
take up solid-state stuff. He keeps talking about the HV power supply on his
bench and that makes me think of how nice it is to work at 12 V.

BTW, I found mountaineering and racing a helluva lot more exciting than
working with vacuum tubes.

Not really. What you say is the general "wisdom".
I want low noise, high (adjustable) gain preselector. Something with below 0.1 uV. There are situations when that is needed (small loops receiving antennas, Beverages on low bands, etc.) The gain should be adjusable so it is (band noise) just above the noise threshold of the mixer for particular antenna/band situation.

At the same time have high dynamic range to handle strong signals S9+60dB without overload.

Way back I modified Drake R4B by putting 6EH7 as preselector with separate RF gain control. It worked very well and it is still hard to beat.

Hi Rick.

There was an article quite some time ago which listed a computer program
for calculating a diplexer of the same type as you show on your website.
Speaking of which, I like how you presented the information about diplexers.
Well done, and easy to understand.

========

I am not sure if you will be able to get a copy of this article, but it
was from:

'PROGRAM BY JEAN-LUC DUGAS
'NOVEMBER 1986 R.F. DESIGN PAGE 97

The program allows choosing Highpass/Lowpass or Bandpass/Bandstop.

According to the RFdesign website, they plan to eventually have archived
online back issues, but so far they only go back to 1999.

Anyway, here is the archive website:

12V, holy cow!
If I go low voltage I keep it at around 5. I am building a controller board
with basic stamps and recently fried an A/D chip by letting it have 12V, it
was lethal.

By the way, talking about overload. The issue of crystals breaking has been
mentioned a few times, but how do I measure what the crystal "sees" for
current and what is tooo much???

Bob gave a very good explanation. I'll add that the term "enameled" is a carryover also. I doubt that real enamel is used any more, and that "enameled" wire is actually coated with plastic these days. But we still use the term to describe wire, usually solid, with a very thin, usually transparent, coating. And because it's by far the most commonly used wire type for winding coils, "enameled wire" and "magnet wire" are often used interchangeably.

Roy Lewallen, W7EL

While you definitely need the lowest noise figure and a high gain when using small magnetic loops, I very much doubt that you are going to need the strong signal handling capabilities for these antennas. Why not use a dedicated preamplifier constantly attached to these antennas, possibly with some protection circuitry to avoid damage when transmitting through your nearby transmitter antenna ?

With modern transistors you can get quite noise figures, however, some transistors may obtain those low noise figures only at UHF and above, since the 1/f may start already in the MF or HF range.

One other thing to watch when using devices with gain up to the microwave bands is the direct pick-up of local FM and TV signals, unless the circuitry is well shielded and the input filters contains capacitors with low parasitic inductance.

Just switch the receiver input between the magnetic loop preamplifier output and the full sized antenna and avoid the hassle with variable gain stages.

>At the same time have high dynamic range to handle strong signals S9+60dB
>without overload.

You are going to encounter such signals from a full sized antenna, but even at 14 MHz, the band noise is still quite high, so the ultimate noise figure is not so important.

By the way, did you check the "A High-Dynamic-Range MF/HF Receiver front end " by Jacob Makhinson N6NWP (QST February 1993 p. 23-28, with corrections in June 1993 p. 73) ?

It contains push-pull preamplifier designs with feedback with nearly +33 dBm input IP3 and gain compression starting around S9+80 dB.

I've not tried it as I can't find any suitable sheet metal, but
aparently if you score the inside of the fold line with a scalpel
blade then the bend goes easier.
Where are you finding the sheet tinplate?.

Actual enamel is more easily chipped off, and a blade will scrape it
away from where you wish to solder.

The newer plastic coating is nearly indestructible, resisting scraping
with a blade, soldering iron heat, and most solvents. There is a
special solvent (rather nasty one, IIRC) which softens it up enough to
remove. Otherwise, power tools, flamethrower, or something really
serious is needed to remove it.

The simplest way is to get the special solvent, but go generous on the
ventilation.

The tool used in machine shops for this is called a "sheet metal
brake", and will do all that you are asking for, partial width folds,
exact angle bends, etc.

You might find a small used one out there, but looking at a picture of
one will give you ideas for a home version.

There are plans for building one, which might be best for you, as you
can readily scale everything down.

Acceess to a machine shop for some of the parts would help.

The enamal is often "formvar." Check this out:
http://www.reawire.com/formvar.asp

Kapton had been used for this also.

But this would be for high end uses. The cheaper ones may actually be
varnish! As it is thin, it will bend with the wire unless the angle is
really acute. You don't want two cracks aligning with each other. But
this is the luck of the draw.

I actually used a specialized microscope at one time which allowed a 360
degree view of the wire. You would spool it through and look for
defects. Who would do this? The space program and the military for very
high reliability equipment.

Al

You can use a panel lamp in series with the crystal to limit the current (too much current causes the lamp to glow, increasing the resistance, limiting the current)... Check some of the earlier handbooks for the proper lamp to use... A 47 might be a good start. This is really a bigger problem when crystals other than the older pressure mount FT243 are used (modern plated lead connections) or with larger PA tubes used as oscillators (6L6, 807, etc.)

What makes you think I don't? I've horsetraded quite a few BAs in my time, many of which stuck around for my own use. My point was, and is, for the time spent, there may be greater rewards from pursuing a different aspect of the hobby. Ie, he's stuck on mountain climbing, and he might enjoy racing, too.

I find it fascinating that some people project my concerns about obvious newbies fooling with HV into a condemnation of trying something different, especially when 'trying something different' was my point from the outset.

Uwe is certainly as free to accept or disregard my advice as I am to give it.

Too crude. I've been into radio and electronics since I was about 15
years old. Back then, my main source and supply were the WWII surplus
electronics stores and the garbage bin at the local radio/TV repair
shops. Fishing tubes out of the trash and retesting them in the tube
tester was my main source of tubes. Henry Radio's dumpster supplies
much of collection of RF related items.

Circuit boards were often found with the parts I needed, but
unsoldering was tedious. Eventually, I hit upon the proper method. I
clamped one edge of a circuit board into the bench vice on my fathers
workbench, heated the solder side with a propane torch, pulled back on
the board to apply tension, and released the board when the solder
sorta melted. Parts, pieces, and solder would spray all over the
place. I could empty a board full of IC's in about three tries.

The problem was that I wasn't very careful about where the solder
"spray" went. When my father arrived to use his workbench, there were
components and solder blobs imbedded in just about everything. We
spent all day cleaning up my mess. I was later informed that I could
have burned the garage down (but I doubt it). I also wasn't into
wearing safety glasses and was lucky not to have blinded myself. At
the time, extracting parts for projects was deemed more important than
simple survival.

On orders from the high command, the propane torch became off limits,
and I was back to tediously removing components one at a time.

When I eventually went to college and later employment, I again used
the propane torch and springy circuit board method to extract
components en mass. I wore safety glasses and caught the parts in a

large cardboard box.

However, as components and boards became smaller, the method no longer worked. Small thin boards just don't have the spring in them, and SMT parts just don't have mass to be easily launched. Components on both sides means that one side gets ruined in the process.

From: k7itm@aol.com
Message-ID: <3200347.0404041107.5d48eade@posting.google.com>
Source record: 27170

The tuner I mentioned did the cascode specifically to achieve low
noise and the ability to handle big signals with low distortion.
Somewhere in my disorganized archives I think I have more info on it,
but don't ask me to look! ;-) As I recall, they used a transistor
billed for CATV service with low noise and good linearity on the
input, and an RF power mosfet on the output--one of the old Siliconix
VMOS ones?? Haven't looked at it in 30 years, so I hope you'll excuse
my lapses of memory. In general to get low distortion, expect to have
to use fairly high current levels.

Do you have specific requirements? You may well be able to do fine
with a different, simpler design. I'd submit your requirement is not
for a cascode, but for specific TOI and perhaps harmonic performance
and noise level and input and output impedances.

Cheers,
Tom

Also old tv focus coils and deflection yokes.
I've also torn up old transformers to rewind them
and saved the wire.
I've made a few filter chokes out of old filament transformers.
I pull out the E I core pieces, unwind the secondary, and add more
wire to the primary. Then I reassemble the core, with all the E pieces
going the same way (single air gap since a choke see mostly DC).
Radio Shack filament transformers are wound on a plastic bobbin which
makes the job easier. I've gotten about 7-8 henrys out of these,
good filter chokes for tube equipment.

Heh heh heh...you low-voltage kids are all alike. Us vacuum veterans
would not think twice about the +120 VDC (the "B+") in the old
"All-American Five" cheap table model AM BC radios.... :-)

>By the way, talking about overload. The issue of crystals breaking has been
>mentioned a few times, but how do I measure what the crystal "sees" for
>current and what is tooo much???

Seriously, folks, the websites for International Crystal, Corning
Frequency Control division, etc., all give specs on various sizes
and cuts of their quartz crystal units. Few really "measure" the
crystal drive levels since that can be done analytically...if one
knows how to do this. If not, there are several hints on the
various crystal unit websites for approximating that, such as
typical circuits.

The best approach at the beginning is to take advice from others
on what works and what doesn't...such as the old, old FT-243
holder crystals can take more power dissipation (thicker slice of
quartz) than most of the smaller HC-6 holder units. The newer
SMD quartz crystal units have very low power specs and should
not be used with most vacuum tube circuits because of that.

Having been in the electron-pushing racket for better than a half
century and bridging the tube and transistor eras, I've never
experienced any quartz crystal physically "breaking." If a
quartz crystal circuit stopped working, the quartz unit just sat
there without a sound, same as it did when it worked OK. :-)
Only the oscilloscope trace knew what was in the hearts of
such circuits...

The mixer section is what is REALLY impressive about that front end.
There was another article (also in the handbook) about a similar mixer
that used a siliconix quad dmos fet that was even better.

Good link still! It's a 10.0 MB file so takes a bit on a POTS line,
like a very long lunch while the computer does its thing.

LOGSA has a bunch of TMs which are slightly militarized versions
of the original commercial models...including a Collins KWM2
(as AN/FRC-93) and a Tektronix 475 oscilloscope. :-)

The "A" in the full-identity URL seems to be an indicator that it
will download to anyone. Any "B" to "D" is going to demand a
Log-On ID from a registered person...don't try to hack it. :-(

Mike - I've found the LOGSA site to have an extremely fussy
search engine that didn't turn up your valid link, at least in the
main search window. I know the individual CD listings can be
found by the little direct link at bottom of page, that to get the
various EM numbers (of the CD) or other ID by NSN, etc., but
not by standard nomenclature. Can you point in the right
direction to find something like that?

I have found that putting the wire in a flame and then sanding it works.
But, you are right it's very hard to get off. I wish I cound buy
enamelled wire some place

I realize it's the wrong side of the pond, but DigiKey lists them, however they appear to be out of stock on the 47pf. Minimum order quantity is 10, but the most expensive is 14 cents U.S. Unfortunately, between the minimum order and shipping they would turn out to be mighty expensive for you. The prices don't seem to go down with quantity as fast as resistors. For example, the 100pF is 88 cents for 10, $6.80 for 100.

Seems like people are using monolithics a lot more these days, but they are a lot more expensive.

ESR (http://esr.co.uk) stocks them, I don't think they are BC though.

You could use 680 series ceramic plate. Rapid Electronics sells them.

The idea is to have one preamp or RF stage for whole range of antennas 160 -10 or 6 m. No outboard boxes, preamps, but one good "in house" adjustable gain amp. No step or switchable attenuators either. Normal city mortals have high band noise levels, but when you go to the ocean front, use RX antennas or beam north on high bands, you need sensitivity and of course high dynamic range for the other end of the signals spectrum, like operating in Multi/multi environment.

Thanks for N6NWP article info, I will look it up.

Low noise, high dynamic range, strong signal handling.
Again, useable for low signal RX antennas and handling strong in-band signals
like in multi/multi situations, when you want to tune/scan the same band while
transmitting on that band.
Filtering and protection is another story.

Low noise mixer is to follow, with low phase noise synthesizer.

Trying to beat K2 and Orion front ends.

2697. Frame - vs. Magnetic antenna ?

Newsgroup: rec.radio.amateur.homebrew

Hi

wonder if it is some particular difference between the terms "magnetic antenna" and "frame antenna" ? Somebody seems to have the opinion that the second is just a popular new word for the first, and it is no real difference. I would believe that a frame antenna could be a single winding antenna with high impedance connection on to the grid or gate of an amplifier or mixer, while the magnetic version has inductive coupling.

I've tested some of the latter type on 136kHz and MF, and it seems that it is no need for an amplifier to improve the signal, it only lowers the signal to noise, and possibly put too strong signal into the receiver. On 136kHz the tuning is extremely sharp, and remote control is a must, see http://home.online.no/~la8ak/L2.htm , if a large frequency range should be covered, use two varicaps should be connected in electrical-anti-paralell (not DC), it is easily possible to cover the 500-1600kHz band with remote tuning.

I really suspect that it is outlined an amplifier which it is not expereinced whether it is needed or not, I believe it is no need for extra amplification below 15 or 20MHz, and since the frame antenna is relatively narrow banded it is no need for particularly good IP3 characteristics on any frequencies

Somebody once mentioned that a transistor with 50mA collector current equalled a valve amplifier with 5mA anode current in respect of IP3, wonder such is likely to be true? Suggested valve is 6761 with gm=50mmho

It's not easy to measure crystal current, since it's RF current at the crystals frequency of oscillation. Most AC milliameters will stop working at about 10Khz, and the lead length and impedance will probably throw off your oscillator.

One "trick" we used in the old days, which also sometimes saved the crystal from destruction, was to put a low current pilot lamp in series with the crystal. Seems to me it was a #49, but you'd best look it up. My recollection was that this was a 60ma bulb. In normal operation it should not glow visibly.

I'm sure the terms must mean slightly (or more) different things to different people. To me, a "frame antenna" is a loop which is specifically rectangular (or square) like most common picture frames, but could possibly have a perimeter that's a significant fraction of a wavelength. And to me, a "magnetic antenna" (as opposed to a magnetic-mount antenna) is a loop which might be a frame or a circle, but has a perimeter which is definitely quite short compared with a wavelength, so that it has low response to electric fields. Both are "loop antennas," and the magnetic antenna is often called a magnetic loop. To be clear, you might say, "square magnetic loop" or "circular magnetic loop" or whatever, and get even more specific by calling out the perimeter in wavelengths.

Cheers,
Tom

Are you getting a "dip" in plate current? If not, the coil is probably too
large or too small. Unless you get a real dip, the output network isn;t right.

I have used a very similar transmitter with 350 volts on the plate, and the dip
is clean and pronounced.

>Nobody

It is quite possible that the receiver is being overloaded by the large signal
and creating a chirp.

> is clean and pronounced.

Jim, the original docs I got for this tx call, at 40 m, for a 15 turn coil
on the coil form provided with the kit, which I hear was 1.25" diameter.
If I use the formula for air coils this turns out to be roughly a 22
microhenry coil.

The coil which works best with my tx is 8 turns on a 1,125" ceramic core.

To get guess work out of it I just bought and built a L/C meter and
measured my coil to have 2.7 microhenry. So I am way off, but it works, sort
of.

The air caps are 36 to 420pf at the plate and 15 to 728pf at the antenna, so
that seem right.

All this happens with B+200V and 35 mA plate current.

Older ARRL handbooks give typical values for pi network for 50 Ohm antenna
loads and my values are in range for the caps but my coil is too small.

The ouput voltage on my antenna measured with a scope is up to 75 volts peak
to peak, with a 50 Ohm load that would mean I get more out of the tx than I
put into it and I am not of the sort who says this might happen.

So my conclusion is, and tell me if this sounds right, that I have an
antenna which is far from 50 ohm resistive at 40m and that that makes
everything weird.
The dips in plate current are nearly imperceptible and they are not aided by
my 250mA full scale meter. They may be 2 or 3 mA.
I tune with the help of my scope.

> I tune with the help of my scope.

The pi network should be able to match a wide range of impedances but it would help to connect a known resistive load. Five, 2-watt, 270-ohm resistors in parallel would be close enough. If you're getting a dip in plate current the circuit is resonating somewhere, and you say you've worked people, so it's putting some rf on the band.

See if you're getting two dips. A lot of those pi networks would resonate on the operating band with the plate tuning cap almost completely meshed, but there was enough range in the cap that it would also tune to the second harmonic. If your LC meter is right you may be dipping at a harmonic, not the fundamental.

OTOH, if your calculation of what the original coil was is correct, the plate tuning capacitor should resonate when its value is about 20 pF -- for a 22-uH coil. That doesn't mesh with the range of your plate tuning cap. A 2.7 uH coil would resonate with the plate tuning cap at about 185 pF, which seems more reasonable.

This is one of those rare occasions when a grid-dip meter is handy. Is there a ham club in your area? Someone may have one to lend. Meanwhile, hook it up to a dummy load and see what you get.

There's something else you could try, but I don't know how well it would work. With the AC-1 unplugged you could connect your receiver antenna to the top of the plate tuning cap and adjust the plate tuning cap while listening for a peak in the noise level. That would tell you the circuit was resonating at 7 MHz. If NG, try 20 meters and 10 meters.

In the olden days I had a 6BE6 connected inside my Viking Valiant, such that it turned on and bridged the receiver antenna input when transmitted rf appeared at the grid. When the key was up, rf from the antenna passed into the receiver. This allowed for full break-in CW, and I could dip the plate tuning cap just by listening to the noise level. Real handy when moving around the band in a contest. You would probably pop the front end of a solid-state receiver doing this, so don't try it. The circuit was in an old Radio Handbook, which was edited by Bill Orr, W6SAI. That's what made me think that you could try this with your receiver, but exercise appropriate caution.

You know, I think you can get coil forms to fit your rig from Antique Radio Supply, and also maybe Ocean State Electronics (oselectronics.com). You could even make one for 30 meters. Ocean State has a power transformer in their catalog that may do for a power supply for your rig, too. Or look for an old tube-type hi-fi receiver in a thrift shop or at a tag sale. If you're going to do, you may as well do it! :>

No broadcast stations, but the FCC database shows 5 amateurs in Hell,
Michigan.

For those of you searching your maps, it's right between Chalkerville and
Pinkney.

The original post was not clear as to what frequency he was hearing the voices on. Was it 75 meters? Sounds to me like a normal band opening on 75.

Hmmm, I wonder how many Hams there are in Paradise, MI?

> microhenry coil.

22 microhenries? I get more like 8 microhenries using the formula

L = (a * a * n * n)/([9 * a] + [10 * b])

where
a = radius of coil in inches
b = length of winding in inches
n = number of turns

> The coil which works best with my tx is 8 turns on a 1,125" ceramic core.

But do you get a dip?

Be aware that the AC-1 went through some changes in its lifetime. Some
models used a filter choke, others did not. Some used a 730 uuf
loading capacitor, others just a single-section 365 uuf one. Coils
changed too.

> To get guess work out of it I just bought and built a L/C meter and
> measured my coil to have 2.7 microhenry. So I am way off, but it works, sort

> All this happens with B+200V and 35 mA plate current.
>

LC = 25,330/(f * f)

so for 7 MHz, the LC constant is 516. Your 2.7 uH coil should resonate
with 191 uuf.
>
> Older ARRL handbooks give typical values for pi network for 50 Ohm antenna

That's defintitely part of the problem. What antenna are you using?
Have you tried a resistor or lamp load?

> The dips in plate current are nearly imperceptible and they are not aided by
> my 250mA full scale meter. They may be 2 or 3 mA.
> I tune with the help of my scope.

The meter tells more. You can use a pilot light (#47, 150 mA) instead
of a meter.

Sudden thought: Where is the meter connected? Are you reading plate
current, or plate-and-screen current combined?

Here's something else to try:

Often trouble of this sort is due to the RF choke used. What RFCs are
you suing, particularly in the plate circuit? Although the LC meter
may say they are a certain L, in real life they may have all sorts of
unwanted resonances.

To test this idea out, do the following:

- Remove the plate RFC
- Connect the antenna end of the plate coil to the B+ where the RFC
used to be connected. This point should already be bypassed to ground
through a disk capacitor of about .01 uF
- Disconnect the "loading" capacitor
- Remove the plate coupling capacitor.

What you will then have is the 200 volts being fed to the plate
through the coil, with one end of the coil going to the plate supply
and the other end connected directly to the plate of the 6V6. The

plate tuning capacitor is connected between the plate of the 6V6 and ground.

End result is no plate RFC and a parallel resonant circuit. There's no connection for an antenna yet, but that's not important right now.

Test out the rig and look for the plate current dip. It should be very obvious because there is no load connected.

This is just a temporary setup to see if the RFC is OK.

It might work, but it will not perform as well as if made with wire
with thinner insulation. You will not be able to get as many turns of
wire on the rod, and those turns will not be coupled together as well.

Message-ID: <u05670dpn33fmcf7752dcm5did3l0skje3@4ax.com>
Source record: 27115

I've seen a bunch of cases where a 10Ghz gunn
diode was used for full duplex, with a split IF.

Has any one seen a similar scheme work at lower frequencies?

I want to create a small and light weight full duplex data radio.
This is for my RC powered solar plane.

So one end of the link will be airborne and the other end will be fixed.

I'd like to aceive:
20 to 40 miles LOS range.
9600 baud data throughput.
<1W TX power. (To comply with FCC Ameateur RC control rules.)
<1W total airborne power. (To minimize power loading)
Very light weight.

Tracking gain antenna is ok on the ground side.
Airborne antenna needs to be omni.

Any ideas or thoughts?

Paul (KL7JG)

2729. Air-dielectric variable capacitors

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-06 21:02:49 UTC

Message-ID: <pan.2004.04.06.21.02.48.347005@ubgznvy.pbz>
Source record: 27116

Hey folks. I've had my license for just a couple of weeks now. The only equipment I have at the moment is a Ramsey 2m receiver kit I bought years ago. Largely for economic reasons, I'm attempting to build a 40m SSB receiver from schematics in the ARRL Handbook. The first item I'm looking for is the tuning capacitor. I searched through the list of distributors from ARRL's site, and found some candidates in Antique Electric Supply's catalog. Here are the notes:

* Ball bearing mounted shaft
* Gear drive vernier
* 1/4" flatted shaft
* Body is 1-1/4" high x 1-1/8" wide by 1-7/8" long.
* 15 plate section @ 200 pf with trimmer
* 5 plate section @ 30 pf with trimmer
* 13 plate section @ 85 pf with trimmer
* 5 plate section @ 25 pf (no trimmer)

They're priced right ($6 each), but I'm brand new to this, so I want to verify that I can use these. The schematic calls for a 30pF cap. For multi-section caps like these, are the sections isolated from each other to effectively be their own component? In other words, can I just hook up the 30pF 5-plate section and leave the rest alone? (And for future reference, could I hook multiple sections in parallel to create additional capacity possibilities?)

Thanks,
David Murphy
AB8SO

Typically they have one set of plates in common (usually the ones
attached to the rotating stator). Each section has a second set of
plates, insulated from the frame and from the other sections.

> In other words, can I just hook up
>the 30pF 5-plate section and leave the rest alone?

Yes - use the (common) stator connection, and the connection
for that one section's isolated plates. There may be a very small
amount of parasitic capacitance between the section you're using and
other sections - it's probably not enough to matter in any way.

> (And for future
>reference, could I hook multiple sections in parallel to create additional
>capacity possibilities?)

Yes.

Too Cool!

Torch and pliers with through-hole. Just pull off what you want.

When I was pre-teen I needed some wire. I found some...it was on the coil
of my dad's T/R relay...on the rig he had been using! I think it was a
common "telephone" relay, so not a really big deal to replace the coil, but
he had a fast break-in system using these relays and it probably was
carefully adjusted to sequence the contacts for Rx, Tx and antenna
switching. Don't remember the consequences. Maybe the concussion wiped
out that memory (just kidding).

I am putting a VHF/UHF antenna in my attic and have run coax into two different rooms in the house. I would like to be able to access the antenna, on both bands, from both rooms in the house (not at the same time, however). Is there a "remote" way I can do this, meaning without running any more wires? I have been searching for an rf triggered relay that would ground the second coax when a signal came down the first, but I can't find anything like that. A duplexer won't work because I want to be able to access both bands from both rooms. Certainly there is someone else in this hobby who has done this, but I can't find anything on the Internet about it!

ANY suggestions would be welcome.

My recollection is hazy but I seem to recall that when the loading cap was
open too far for the load the pi net was seeing, the dip got very shallow.
I'll bet his antenna is outside the range it can match. Time for Uwe to
gather up some of that coil-winding stuff and make a tuner.

A duplexer is a set of quarter-wavelength sections of transmission line. On
10 meters your duplexer elements would be about eight feet tall. Are you
sure you want one for HF?

If you google for "2 meter duplexer" you will find quite a few plans on
websites. Most people avoid the trouble of making their own and just buy a
set.

I have one which has a input for 0-90Mhz then 120-500Mhz on the other side,
and it puts them both onto one coax line. Is that called a duplexer as well
or is it called something else ?

I've seen them called 'splitters' or 'combiners'or 'diplexers' before
now, perhaps not accuratley, but it is what they do.

How big is the plane that you can see it from 20-40 miles? Is it the
Spruce Goose or what? Are you trying to make an RPV for the military?
Why do you need full duplex? Are you just trying to collect data from
the airplane? I'd have to double check, but I don't believe it's legal
to "control" the plane on 10 GHz.

How about this untried idea.

A latching relay.. switched by a battery in the loft.
When you PTT up coax 1 a transistor is biassed to pull
the relay across to that coax and disconnecting the other
coax. I larg-ish electrolytic capacitor and resistor in
parallel as the relay sink, so the relay current drops off
to almost nil once it's changed. This would reduce overall
current drawn from the battery.

I wonder if something like that would work well?

'Duplexer' is a term used to describe devices that provide greater isolation between the ports than what you seem to have. They are used on repeater stations where the transmitter and receiver operate simultaneously on frequencies close together. The transmitter is producing anywhere from a few watts to several hundred watts, and the receiver cannot be 'desensed.' The duplexer acts as a sharp filter as well as a combiner, allowing both units to use the same antenna.

There are other names for similar devices, which vary in sophistication. The simple TV-antenna splitter allows two receivers to use a common antenna, but you don't get much isolation between the output ports and you wouldn't transmit much power through one. There are power splitters and combiners that you can buy or build. As you have not stated the application it is impossible to tell you what you need. Could you be more specific about what it is that you are intending to do with this device?

Well, the way I use the formula is 1.25*1.25*15*15/((9*1.25)+(10*0.45)) =
351.5/15.75 = 22.3

0.45 is the length of the 15 windings.

Do I not use the formula properly??

My meter is built into my bench power supply (thats why it reads up to 250mA), so I am measuring plate and screen current.

I put in a second meter which would only measure the plate current but its reading is practicly identical to the first one, as if there was no grid current.

My antenna is a dipole of about 75ft. length each side, connected with a 50 ohm coax, no balun or such things.

I will need a few days to try out some of the things you and also Paul suggested and it might really be a good idea to get an SWR meter and a tuner.

All in due time and I will surely get back to you.

Thanks for the help

Uwe

Source record: 27138

I want to do it on 6M.
I'm asking about a fullduplex link, "Like" is done with the 10Ghz Gunn.
I don't intend to use 10Ghz.

Fullduplex:
Control up link, and Telemetry downlink, GPS position, Altitude Airspeed etc....

I'm currently doing this with a 6M TX and a 900Mhz telemetry Tx, but it makes for two antennas,
two radios in the plane etc.... I would kill for 100gm less weight.

As for range, I'm trying to set some FAI records with the plane.
See:
http://records.fai.org/models/ Select the subclass:
Sub-class F5-SOL (Aeroplane, electric motor (solar cells))

The current Model Altitude record is about 7K ft.
I'd like to do 10K and with some wind it could easily get several miles down range.
Thus 20 miles to have some margin.

Last Years Plane (With less efficient cells.)
Launch: http://www.rasdoc.com/splinter/DCP01221.JPG
Proof it flies: http://www.rasdoc.com/splinter/ItFlies.JPG
Plane has 144 inch span and weighs about 2Kg or 4.4lbs.

>or is it called something else ?

These things are often mislabeled in their use. But then it depends on
how you look at them as to what to call them.

A duplexer is what some antenna manufacturers call a device that
allows feeding a two band antenna with two different transmitters/
receivers. Not necessarily at the same time.

A duplexer is commonly known in the two way industry as a device that
allows transmit and receive simultaneously on a single antenna.
Different frequencies.

A diplexer is usually a device that allows two transmitters to operate
simultaneously on the same antenna. Much the same as a duplexer works
but since it only involves transmitters it is called a diplexer.
Sometimes called a transmitter combiner.

You can use a duplexer to combine two transmitters into a single antenna and operate simultaneously. You would then be operating it as a diplexer or transmitter combiner.

There are also splitters (tv industry) that allows two or more receivers to operate from one antenna. In the two way industry they are commonly called power dividers or receiver multicouplers. They provide about 20 to 25 db of isolation between receivers.

If you build a "splitter" that can handle more power you can turn it around and combine two or more transmitters into a single antenna. In the two way industry these are called hybrid combiners. This method of combining transmitters is often used when frequency spacing is very close. Too close for cavities to separate the signals. Losses are higher than with cavity type combiners or duplexers.

A duplexer cavity does not have to be a full quarter wave length long. Those are the most efficient however. At higher frequencies (800 mhz for example) cavities are often 3/4 wavelength long. They work better than the 1/4 cavities.

There are also folded cavities where the inside of the cavity is folded back on itself to reduce its length.

There are also loaded cavities. These are part cavity and part helical resonators to reduce the length.

There are duplexers for vhf mobile work that are about 6" long with 1" square cavities. These are quite common. They do not have the same amount of rejection as the larger full quarter wave types do however.

There are also duplexers that are built from just sections of quarter wave coax lines rolled up and put in a small box.

The type of duplexer needed depends on the amount of isolation needed between transmitter and receiver. The amount of isolation required depends on the spacing between transmit and receive frequencies.

But to answer your question, yes what you have may very well be called a duplexer.

You used the coil *diameter* where you should have used the coil *radius*. A coil with diameter of 1.25 inch has a radius of 0.625 inch.

Compute

0.625*0.625*15*15/((9*0.625)+(10*0.45)) =

and see what you get.

>ohm coax, no balun or such things.

150 feet total length? That's not resonant on 40 meters, and your SWR with 50 ohm coax is probably quite high.

A half-wave 40 meter dipole is about 66-67 feet long (33 feet each side), and will have a fairly low SWR on 40 meters when fed with 50 ohm coax. The next length that will give a fairly low 40 meter SWR is about 205 feet overall (102 feet each side). Such a dipole is one-and-a-half waves long.

These are "ballpark" figures, not exact ones.

How high is your dipole?

I agree with Paul Morphy that a simple dummy load is best for testing. His suggestion of paralleled noninductive resistors is excellent.

>I will need a few days to try out some of the things you and also Paul
>suggested and it might really be a good idea to get an SWR meter and a
>tuner.

That will work, but first get the rig working correctly into a dummy load.

>All in due time and I will surely get back to you.

If it takes me a while to respond, it's because I'm away from the computer.

Actually I have one from comet with a 1.3-30Mhz input and a 49-470Mhz and
it is labeled as a duplexer.

A diplexer is only for combining 2 transmitters only i believe right ?

>
> "PM"

Ok Here is the run down.

I have one "duplexer", which is what it is labeled as from comet, that has 2
inputs for 1.3-30Mhz and 49-470Mhz

and i'm needing / wanting another one for the following purpose.

I have one run of coax going from my radios to outside where my antennas are
and I need to try to use the coax for both HF and for VHF/UHF SO I need a
one of these devices inside at the radio end to get both HF and 2m/440 onto
the coax.. then another one at the other end to split it off again to goto

seperate antennas.

Anybody have an idea how to determine what material a surplus toroid core might be made out of? I tried winding a known number of turns on one and then measured the inductance on a Q meter, but how would that relate to the the permability factor?

Probably the easiest way is to compare your inductance to tables of
inductance for various core types in your size.
http://tritium.fis.unb.br/Fis3Exp/fcim.csdc.com/fcimis/compid/ind/toroid.html

Or you can go back to the basic physics and solve the formula for
permeability.

This is part of the description of a "Microwatter" from the 2003 ARRL
Handbook:

"This simple, easy to build terminating microwattmeter by Denton Bramwell,
K7OWJ appeared in June 1997 QST. It can measure power levels from below -50
dBm (10 nW) to -20 dBm (10 uW) with an accuracy of within 1 dB at
frequencies from below the broadcast band (540-1720 kHz in the U.S.) up to 2
meters."

The circuit uses a Burr Brown INA2128P amplifier; the Handbook says the part
is available from DigiKey but they are showing it as obsolete and out of
stock. That's dual instrumentation amplifier, specs here:
http://web.ics.purdue.edu/~fryecm/ina2128.pdf so perhaps there is a
more-recent and available chip that will work. From the datasheet:

"The INA2128 is a dual, low power, general purpose instrumentation amplifier
offering excellent accuracy. Its versatile 3-op amp design and small size
make it ideal for a wide range of applications. Current-feedback input
circuitry provides wide bandwidth even at high gain (200kHz at G = 100).

"A single external resistor sets any gain from 1 to 10,000. Internal input
protection can withstand up to ±40V without damage.

"The INA2128 is laser trimmed for very low offset voltage (50 mV), drift
(0.5 mV/°C) and high common-mode rejection (120 dB at G ≥ 100). It operates
with power supplies as low as ±2.25V, and quiescent current is only 700 mA
per IA-ideal for battery operated and multiple-channel systems."

I'm betting someone here knows a sub and hoping they will post it because
I'd like to build one of these myself. The only other uncommon part is a
CA3039/NTE907, IC diode array, of which two diodes are used.

Going to 1 W would be a simple matter of using a calibrated attenuator.

They aren't cheap, I noticed that. Probably all of 3/10 of a Euro to make.

Maybe this will work:
http://home.datacomm.ch/hb9abx/diplhf6m-vuhf.html

Says he got up to 100 W on HF and 50 W on 70 cm. He has an email address,
too..

==========

Enter core dimensions, number of turns and permeability of core material
into program TOROID to obtain coil inductance.

Alternatively, do the reverse, measure inductance and obtain permeability of
the core material.

Covers square rings, tubes, flat discs and washers.

Also obtain value of capacitance to resonate coil at a particular frequency.

Download program TOROID in a few seconds from website below and run
immediately.

Check this out:
http://www.webx.dk/oz2cpu/radios/miliwatt.htm

It is based on Analog Devices' AD8307 chip. You can skip the PIC part if
you have a reliable DVM!

Happy Easter, if applicable

Source record: 27012

Jim, after my calculation of the coil were wrong I thought it was about time to check everything and I did and to try and distinguish between radius and diameter...

Using the L/C meter I wound a proper coil, I checked the calibration of my plate current meter, I did a more thorough check of the grid current (it is between 1 and 2 mA) and so on and so forth.
And I did connect a dummy load (even though they don't respond or send out QSL cards when you tranmit into them).

None of the thing did make any real difference and the dip, the elusive dip, was in the order of magnitude of maybe 2 mA, nearly impossible to see on my meter.

Then I changed the circuit around as you suggested, testing the RFC and I got a dip the likes of which I had never seen. The meter went slowly from about 30 mA to 50 mA and then dropped to about 25 mA, I couldn't miss it.

But what does it mean. I gather my RFC is not ok. What is wrong??

I used a Series 4590 high current filter inductor I had around, it has the Digi Key number DN 4528.

Happy about the dip but still not clear on the deeper reasons...

73 Uwe

The RFC you're using is not meant for the appliucation. It's intended for much
lower frequencies. You can't tell that just by looking at it.

RF choke design is a matter of compromises. For example, the use of a powdered
iron or ferrite core will raise the inductance. But that same core does not
work at all frequencies, and may saturate from DC current in the core.

The biggest problem is called "distributed capacitance". In order to get lots
of inductance, you put on lots of turns, closely spaced. But each turn has a
small amount of capacitance to the turns next to it. All these small
capacitances add up, and as the frequency is increased they become significant
to the total reactance of the choke. At one or more frequencies the choke will
actually resonate - these are called "self resonant" frequencies. At some
frequencies the choke may act like an inductor of much lower inductance, or
even like a capacitor, because of the self resonances. Self resonance in a
choke can be found with a suitable dip meter.

RF chokes that are meant for applications like the AC-1 are designed to have
self-resonant frequencies far from the amateur bands.

>Happy about the dip but still not clear on the deeper reasons...

Hope this helps.

A nice chip the AD8307, very easy to use. I used one as the logarithmic
amplifier stage in my spectrum analyser. It's available at Farnell
http://www.farnell.com in 8-pin DIL, which is another nice thing for a
relatively new IC. Expensive though, and of all the chips I could've fried
when constructing my analyser, I had to fry that most expensive one and get
a replacement. I guess to do otherwise would probably be in violation of
Murphy's law, or Sod's law or someone's.

Hi

need info about active high impedance buffer amplifier for RF probe,
believe Maxim makes such. Made a temporary circuit with discrete
components, it is shown as item #2.16 on my page
http://home.online.no/~la8ak/m2.htm
this is good enough for one purpose, but could well be used for RF
mV-meter covering larger range. If it is available from Linear
Technologies it would be even easier to obtain a sample

A device like this is also known as a "cross band coupler". You might
try a search for that and see what you come up with.

Hello,
I'm building a FM Tx and I'm having some problems to find 100uH RF Chokes here.
So I decide to wind a 100uH air-core inductor, is there any problems on that?
My inductor especifications are:
-Wire: AWG 24.
-Core diameter: 35 mm.
-Spires: 48, 2 layers of 24 spires each.

Thanks,
Hayato

I don't know what your intended use is, but if you just want to measure output power while testing a transmitter, what about just measuring the voltage across your dummy load, since, for the same resistor, power is proportional to voltage squared? (It may take a bit of work/ingenuity to measure RF voltage at six meters, but that's one of the things that being a ham is all about.)

Yes this is all very helpful. Indeed I was thinking that it would have taken me a very long time to figure this out by myself, if at all.

I put another choke in there, a Hammond 1535B, the self resonant min. frequ. is 1.3Mhz.

I guess it does take some deeper inside what parameters to look for since this one improves things slightly but not yet altogether (slightly more pronounced dip).

Who carries the sort of chokes you were refering to?

2789. Statement on Spam and VoteNader.org

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-08 20:43:11 UTC
From: jonas@votenader.org
Message-ID: <a6e149ae.90f4119d@host-69-48-73-244.roc.choiceone.net>
Source record: 27029
Cross-posted to: rec.photo.darkroom,rec.radio.amateur.homebrew,rec.drugs.chemistry,rec.arts.movies.production

Spam from VoteNader.org? (Or naderexplore04.org)

You may have received spam email recently that appears to come from our campaign, or be about our campaign -- perhaps the "From" and or "Reply-to" addresses look like they are coming from VoteNader.org. Or perhaps you have received a message that appears to come from an individual (if the address is real, the real owner probably did not send this email either) with suppressed recipients. Or maybe you received an email that appeared to come from yourself promoting our site.

These messages are NOT from Nader for President 2004, and these email tactics are NOT condoned by our campaign in any way.

UPDATE: Some of the latest forged emails have been made to appear to be coming from naderexplore04.org. Again, we are not responsible for this unfortunate abuse of email, and there is little in the technical sense that we can do to prevent this as it has nothing to do with our actual infrastructure. We are collecting information.

NOTE: The emails with malicious code (viruses, worms, etc.) often have attachments. Our campaign will NEVER send attachments in our announcement emails to you. Please be sure that you have anti-virus software and have the latest updates available for your anti-virus software.

Our hosting service has alerted us to say that Nader for President 2004 appears to be the target of what is called a "Joe Job." Such an event is where a spammer forges email to make it appear to have come from some other domain (such as ours -- or yourself). This is hard to prevent on our end and part of the insecure nature of the email protocol in general.

Members of our actual email list must request to receive email from us (either through Ralph's signup sheets or subscribing during our exploratory phase, or now on our campaign site). When one signs up for email they must reply to a confirmation message before they receive our list announcements.

Our public announcement emails come from "campaign@votenader.org," contain a "Paid for by Nader for President 2004" statement at the bottom, and have "updates@lists.votenader.org" in the "To:" header. Unfortunately, some of these indicators can be forged as well.

Most of the Spam that we have received complaints about appear to be forged from email addresses not associated with votenader.org (often forged to appear to be coming from government email addresses), and have

our website code embedded in the body of the email with hidden tags that contain random words that work to subvert anti-spam software.

If you are on our lists, you can ALWAYS unsubscribe at ANY time by following the instructions included at the end of our announcements. You can also use our unsubscribe page using the email address you signed up with.

If you are receiving this SPAM, we extend our apologies.

We will pursue the spammers to the full extent of the law.

For more information, please review these resources:

How Do I Determine the Source of an Email?
http://www.aota.net/Email_Spam_Prevention_and_Mgmt/emailsource.php4

Why Does This Spam Look Like I Sent It?
http://www.aota.net/Email_Spam_Prevention_and_Mgmt/spamfrom.php4

Coping with a Joe Job

I have a schematic of a device I built for testing and servicing. While mine isn't designed to read in watts or milliwatts, it does detect the smallest amount of RF . There is a pot on it to adjust sensitivity. I'm sure it could be adapted somehow for your needs. Knowing my repairs and such, I'm going to say 3-5 watts pegs the meter. So, as I said, you can scale it back or design the thing to work for you. Cost is about $10 IF you have to buy any thing. It can be made from junk box parts and a spare case from a scrapped piece of equipment or housing from the shack - or just about anything. If interested, e-mail me for info.

Lou

OK, I see what you're up to. SHF Microwave has gunnplexers, etc. The website is at http://www.shfmicro.com/ I believe you will need two gunnplexer modules and two I.F. receivers of some sort to run full duplex. Most people running WBFM on 10 GHz use an I.F. of either 30 MHz (to be used with an HF rig) or 100 MHz (to use a standard AM/FM radio as the I/F. rig. That's the way I ran mine back in the 90's). Hope this gives you a starting point...

You didn't say what frequency the choke will be used for, nor where in
the circuit. But it seems like 100uH is quite a large inductance for
the usual FM frequencies. Winding the choke as two layers will lower
the self-resonant frequency a lot. Even with a very carefully
designed 100uH choke, it will be very difficult to get the
self-resonant frequency up in the 100MHz region. And at 100MHz, 100uH
would give you 62kohms reactance (if you could actually construct it
with high enough self-resonant frequency), which would be more than
you would need in any 100MHz circuit I can think of. If it's a
low-impedance solid state circuit, 100nH might be enough!

Please tell us more. What current do you need to pass in this choke?
How is it used in the circuit? What frequency will it be used at?

Cheers,
Tom

2797. HT transformer value?

Hi guys,

I've inherited a bunch of HT transformers from a an old ham who sadly went silent key a while back. They're all pretty old; typically around 1200V output and on average I guess about 9" cube in size. He used to pick them up at rallies and so forth to make linear amps with. I plan to keep a couple for myself, but if I sell the others, what sort of price should I ask roughly?

2798. RF filters and Impedance Matching

Hi all,

On page 57 of RF circuit Design, Chris Bowick sets out a filter design example. I've posted this to a.b.s.e under the same subject header. He claims that the filter in question - a low pass Butterwoth - matches 50 ohms source to 500 ohms load. However, having checked this out with the aid of a Smith Chart, it appears there is some capacitive reactance present that would require the addition of a shunt inductor to neutralize. However, this would of course totally screw up the filter's characteristics. Upon closer examination, it appears impossible that this type of arrangement could ever be designed without introducing some reactance into the signal path. Or am I nuts? I'd always thought of these kind of filters as being purely resistive overall at Fo but is that really the case? It don't look like it...

Design criteria:

Centre frequency: 35Mhz
Response > -60dB at 105Mhz
zero ripple(!)
Rs 50 ohms
Rl 500 ohms

Of course it isn't. A 1st order butterworth is a simple RC. At its
characteristic frequency, i.e. its 3db point, it has 45 degs of phase
shift in its impedance. Note, centre frequency is meaningless for a LP
and HP. In general the input impedance can be all over the place for a
filter.

Most LC filters are designed to produce the advertised frequency
response, given a resistive generator and a resistive load, but they
don't generally look like nice resistors themselves, at either port.

There are filters designed to look like a resistor, or nearly so,
wideband. Picosecond Pulse Labs, among others, sell such. We had a
thread on s.e.d. a while back, and Jeroen Belleman posted some nice
work, some original techniques to make constant-resistance filters.

I'd suggest looking at www.hammond.com and going to their
relatively new transformer division page. There are prices there
for the "old" tube (excuse, valve) type transformers that they
have available from the Canadian subsidiary.

Hammond products, including the transformer line, are listed
on the DigiKey and Mouser distributor sites here across the
pond...can also be a guide.

To sell "HT transformers" over here, labeling them "high voltage"
instead of "high tension" might be better for getting sales bites.
"HT" over here generally means "Handheld Transceiver." A
9-inch cube of iron and copper might be "handheld" by a
California Governor but few others... :-)

Bon chance.

Hello Paul,
to be honest, the circuit filters exactly as written. It is designed for
an input impedance of 50 Ohm and an output impedance of 500 Ohm.

> However, having checked this out with
> the aid of a Smith Chart, it appears there is some capacitive
> reactance present that would require the addition of a shunt inductor

> without introducing some reactance into the signal path. Or am I nuts?

You are wrong here. I assume that the book doesn't claim to do an
impedance match to 50 Ohm input resistance for max. output power.
It's just designed as a passive lowpass filter with different source
and load resistor having a flat amplitude response. Nothing more.
The input resistance of this filter is for example 5 Ohm at f=12MHz.
According to the seven reactive parts, it has 3 notches and 3 resonances
for the input resistance over the frequency band from 0 to 200Mhz and
an additional zero at infinity frequency.

> I'd always thought of these kind of filters as being purely resistive
> overall at Fo but is that really the case? It don't look like it...

There is always a phase shift at the 3dB corner frequency
of any lowpass filter.

> Design criteria:
>
> Centre frequency: 35Mhz
This the -3dB corner frequency!
> Response > -60dB at 105Mhz
> zero ripple(!)
> Rs 50 ohms
> Rl 500 ohms

>

Paul's filter from a.b.s.e.

A netlist file for the old SPICE people.

```
* Butter50_500_35MHz.asc
Rs N003 in 50
L1 in N001 152n
L2 N001 N002 323n
L3 N002 out 414n
RL out 0 500
C4 out 0 143p
C3 N002 0 153p
C2 N001 0 97p
C1 in 0 21p
V1 N003 0 AC 1
.ac dec 100 10k 200MEG
.end
```

Best Regards,
Helmut

PS: Such filters are analyzed with the .AC command in (LT)-SPICE.

The simulation type: .AC DEC 100 10k 1G
The SPICE voltage source: V1 0 AC 1

V(in) is the node after the source resistor Rs.
The frequency response: Logarithmic Bode Plot V(out)
The input impedance: Logarithmic Bode Plot V(in)/I(Rs)

If you want the output impedance, then you have to add a source in
series with the load RL and stimulate from the output side only.
The output impedance: Logarithmic Bode Plot: V(out)/I(RL)

For the newcomers to this group:

LTSPICE is free SPICE with graphical GUI from www.linear.com/software
There is a special newsgroup for LTSPICE:
http://groups.yahoo.com/group/LTspice/

This is the schematic file of this filter for LTSPICE.
Save it in a file named "Butter50_500_35MHz.asc".

2803. Re: RF filters and Impedance Matching

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-09 20:08:18 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <107e0lkkskbh94d@corp.supernews.com>
Source record: 27040
Cross-posted to: sci.electronics.design,rec.radio.amateur.homebrew

Filters can be lossy or, in theory, lossless. An example of a lossy filter is a first order lowpass, consisting of a series R and shunt C. But let's talk about the passive lossless variety, made solely of inductors and capacitors, since I think that's what you're asking about. In practice, inductors in particular can have appreciable loss, and this complicates analysis a great deal. But for many applications, for example HF filters that aren't too sharp, loss can be negligible for practical purposes. So I'll further simplify things by talking about only theoretically lossless LC filters.

A passive lossless filter can't achieve any frequency selection by means of loss, so it depends entirely on mismatch. Among other things, that means that a passive filter works properly only when both the source and load impedances are the ones it was designed for. A lossless lowpass filter has zero loss only at DC. At DC, or very low frequencies, then, the input is matched to the output. If the filter is designed for 50 ohms in and out, for example, you'd see 50 ohms resistive at the filter input when the output is terminated in 50 ohms. It can also be designed for other transformation ratios -- imagine the same filter with a broadband 10:1 impedance transformer at one end. There are other ways to effect the transformation, but the end result is the same.

But as you go up in frequency, the attenuation of the filter increases. In the case of an LC filter, that means -- it has to mean -- that a mismatch is occurring. The attenuation typically rises slowly and not too much until you approach the cutoff frequency, but there are an infinite number of possible filter shapes, and some can vary pretty wildly in the pass band (the frequency range from DC to cutoff). Butterworth, Chebyshev, and a number of other canonical types have a substantial amount of attenuation, and therefore mismatch, at frequencies quite a bit below cutoff.

An interesting passive LC filter type is a "quarter wave" lowpass filter. It's so called because it mimics a quarter wave transmission line over a moderate range of frequencies. This is a pi section filter (although like any other pi, it can also be realized as a tee) consisting of a series inductor and shunt capacitors. Each has a reactance at the operating frequency equal to the source and load resistance, which for the simple form I'm describing, are equal. This filter is unusual(*) in that it *is* perfectly matched at the operating frequency, which is just below the cutoff frequency. The cutoff isn't particularly sharp, but sections can be cascaded for better high frequency attenuation without changing the impedance match at the operating frequency. It's a really handy tool for homebrew transmitters,

where additional harmonic attenuation is needed, since sections can be added without necessitating output circuit redesign.

(*) It's unusual in my experience with modern filter design, but I suspect this might be a common characteristic in "image parameter" designed filters -- a technique I never learned.

The last sentence should read:

A lossless lowpass filter has zero attenuation only at DC.

The attenuation is often called "mismatch loss", but in the remainder of what I wrote, I use the term loss only to mean dissipative loss -- which "mismatch loss" isn't.

>Who carries the sort of chokes you were refering to?

"Play Things of The Past" (www.oldradioparts.com) is one. Antique Electric
Supply (www.tubesandmore.com) is another. JWMiller still makes pie-wound 2.5
millihenry chokes with phenolic (no iron) cores. Check Digi-Key and Mouser.

Also google "AC1 ameco" - several websites with more info. One site I visited
(whose url I didn't save!) listed the plate voltage as approximately 325 volts.
This site also cautioned that the original grid resistor (47 K?) is way too
high, and that better results are obtained with a grid resistor of 4.7 K to 15
K. The author says the smaller value grid resistor gives less chirp.

The traditional amateur way to measure grid current is with a small lamp in
series with the xtal. "Small" means a #48 or #49 bulb - 2 volts at 60 ma. The
common #47 lamp needs 6.3 volts at 150 ma. and is way too insensitive. Small
flashlight lamps such as used in single-cell penlights may also be useful.

But the lamp should only be used for testing. Its resistance may cause chirp.

and before I forget:

CONGRATS ON YOUR GENERAL, Uwe!

Ooops, my fault.

http://www.hammondmfg.com/claspg.htm

Gets everyone to Hammond's transformer page. Interesting stuff
on links from there.

http://www.hammondmfg.com/

is the Hammond home page with lots of enclosures, chassis, etc.,
plus a link to transformers.

www.hammond.com is indeed the home page of Hammond
Promotions with some good prices on bulk orders of cards
by companies. Was there last week. But for business, not
transformers. :-)

Roy:
[snip]
> The last sentence should read:
>
> A lossless lowpass filter has zero attenuation only at DC.
:
:
> Roy Lewallen, W7EL

Ummmm... no that statement is only true for one type of approximation
polynomial.

A lossless low pass filter has zero attenuation at its' reflection
coefficient zeros.

If it is a maximally flat low pass. a.k.a. Butterworth. then all of the
reflection zeros
are located at DC, but for any other type, e.g. Chebychev, Cauer/Darlington,
General Parameter,
etc, etc... this is not true.

Such a filter will have zero loss at the designed reflection zeros which are
distributed at various
appropriate frequencies across the passband according to the dictates of the
approximation
polynomials.

Aside: Reflection zeros are also known as Return Loss [Echo Loss] poles.
These are the
pass band frequencies of zero loss for lossless LC filters designed
according to modern
insertion loss methods. No one really knows where the reflection zeros of
an image
parameter LC filter are, one has to find them by analysis after the design.
Whereas
with insertion loss design the frequencies of zero loss [the reflection
zeros] are specified
by the approximation polynomials, specifically the reflection zero
polynomial usually
designated by F(s). In fact modern insertion loss design begins with a
specification
of attenuation ripple between zero loss and the maximum loss in the pass
band. The
frequencies of zero loss then become the zeros of the reflection zero
polynomial F(s).

The attenuation in the stop band results in the specification of the loss pole polynomial
P(s) whose zeros are the so called loss poles or attenuation poles. The natural mode
polynomial of the filter E(s) whose zeros are known as the natural modes or sometimes
just "the filter poles" is formed from the loss poles and reflection zeros using Feldtkeller's
Equation.

E(s)E(-s) = P(s)P(-s) +k^2F(s)F(-s)

In the approximation process the stopband attenuation is set first by "placing" the loss poles
in the stopband, i.e. determining the polynomial P(s). Then from the desired passband
attenuation and type of approximation desired; maximally flat, equiripple, etc... the
reflection zeros F(s) are determined and finally from Feldtkeller's Equation and the ripple
factor k, the natural modes or E(s) is determined.

Then the LC filter is synthesized from either or both of the short circuit or open circuit
reactance functions which are formed from even and odd parts of E and F, for example.

X = (Eev - Fev)/(Eod + Fod), etc...

You can review all of this in the very practical and professionally oriented textbook:

Adel S. Sedra and Peter O. Brackett, "Filter Theory and Design: Active and Passive",
Matrix Publishers, Champaign, IL 1978.

Another good practical and professionally oriented textbook is:

Louis Weinberg, "Network Analysis and Synthesis", McGraw-Hill, New York, 1962.

If you can get a copy of:

R. Saal and E. Ulbrich, "On the design of filters by synthesis", IRE Trans. Vol. CT-5,
No. 4, pp.284-327, Dec. 1958.

Bind it firmly and keep it in your library forever... you will have the whole story in a nutshell.

Saal and Ulbrich is "the bible" on LC filter design.

You're correct, and I apologize. In fact, the example I gave of a "quarter wave" filter contradicts the statement about the attenuation. I was thinking of a Butterworth when I wrote it, but as you point out and as my own example shows, there are many other types for which the statement is wrong.

I apologize for the error. Thanks for the correction.

Thanks, Robert (and all else)
I'd prefer a diode solution as there'd be no power supply requirements
for each device. The tiny size is an added bonus, of course. But
what's the drawback with superfast switching diodes as against active
inverters? I'm sure there must be (at least) one...

Thanks, Helmut (and others)
You're right as usual. I'd carried out my checks at 35Mhz which is of
course the cut-off frequency. I'd forgot I was dealing with a LPF and
had proceeded on the basis that 35Mhz was the centre frequency of a
BPF. D'oh!
Sometimes I'm amazed by my own carelessness. No doubt my regular
admirers won't be, though. :-(
I'll do another series of plots for 20, 10 and 5 Mhz later and expect
to see the input impedance point shift accordingly.
Thanks for your sterling efforts, BTW.

2820. Homebrew dipole help please?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-10 14:08:15 UTC
From: Bob <nubob5001@yahoo.com>
Message-ID: <pkTdc.12082$R37.8318@read1.cgocable.net>
Source record: 27057

Hi
We have put together a dipole, each leg is 66 feet. We put a 1:1 balun and it is running about 60 feet of 50 ohm coax. Presently it is about half way up the tower it is intended for so we could check the SWR before getting it up to the highest point. Presently each leg has some lags and dips, no major bends but it is just hanging there, over some bushes and the entire thing is over top of the house, and not touching anything but is very close to some steel guy wires (uninsulated).
Now we can only tune this down to a useable SWR on the 80m band. On all other bands we cannot tune it down to a safe operating range. We are using a good antenna tuner but cannot get anything useable except for 80m. Here we are able to tune the SWR right down.

Questions???
Would we be better without that balun?

Is the fact that the dipole is still too low and close to the guy wires (but not touching) our problem?

Any suggestions please??

Thank you.
Bob

On the other hand, it means that British sports cars have an excellent
safety record. Hard to have a crash when the car is up on a lift.

My inclination is to believe there's something wrong with your antenna tuner. Are you certain it isn't in bypass? (of course, that antenna should be reasonably resonant in the 80m band *without* the tuner, so if the tuner isn't working at all you may well still have a reasonable SWR on 80) Can you get your hands on a 50-ohm dummy load? (try to load up the dummy load through the tuner, it should work on every band)

Can you get the SWR to dip on other bands? (i.e., is it just that the dips aren't deep enough to give a usable SWR?)

What kind of tuner are you using?

Having it low and close to guy wires will affect the resonances and efficiency, but with a good tuner you should still be able to tune out the reactance and get a reasonable match to 50 ohms, at least on *some* bands if not all.

Do you have access to a SWR analyzer?

FWIW, I've had good luck using 44 feet on one side, 88 feet on the other, and a 4:1 balun instead of 1:1. That's the same total length. It gives a decent SWR on every HF band except 160 and 15 meters - and it's close enough on 15 that the autotuner in my rig will match it.

Thanks for the good wishes. Yes I got the ticket and I am out there with my 5 wpm but sometimes I really feel I don't belong there, 5 wpm in the "laboratory conditons" of the test is one thing, out there with all that noise and distraction is an altogether different thing and "stagefright" takes over sometimes.

(www.oldradioparts.com) seems like a good source, I might buy from them sometimes, I still need a transformer for the little transmitter. By the way about specifying these transformers, to get those 320Volt with a tube rectifier do you need a centertapped transformer with roughly 160V in each winding, what they call a 160-0-160??

I did see these other AC-1 sites and yes I do use the smaller resistor parallel to the crystal.

I read a little more about chokes in old radio amateur handbooks and it seems that even their placement in the chassis can be tricky.

I would love to know a way, because even with the 'new' choke the rig is not 'there' yet, to possibly make a test setup for this entire pi section and 'bench test it. Is there such a thing?
If I terminate it with a 50 load and feed my HF generator signal on the input (plate) side this would not be appropriate because the tx and the test generator have a different output impedance??

And what do you want the pi section to do, resonate at the transmitter frequency?

Ways to go...

Hi,

Where is the tuner and where are you measuring the SWR?

Your range of antenna impedances is probably too great
for your particular arrangement. A ferrite cored balun is
not a magic device for matching oddball impedances to coax.
In this case it will be seeing about 50 ohms on 80m and a
1000 ohms or more on 40m.

Also they aren't a simple device but part transformer
and part transmission line and even their 1:1 ratio can be
in doubt unless presented with a certain range of
impedances. The much-used G5RV with balun suffers from this
problem but there at least Louis Varney did pick an antenna
and feeder length/impedance to try to keep the numbers
reasonable.

Cheers - Joe, G3LLV

Hi Bob,

There's someone asked exactly the same question on
rec.radioamateur.antennas & rec.radio.amateur.equipment.

Perhaps you should see what their responses have been.

paul M

2831. filter capacitor in series

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-11 00:31:00 UTC
From: Gordin <Gor_din@noSPAm.co>
Message-ID: <407891ab$1@news.iconz.co.nz>
Source record: 27068

Hello
I know that this may be a dumb question but I have found conflicting info about this on a few web pages.

If one takes say 5 capacitors each with a value of 500wv @ 150uf and connects them in series the result wold be 2500v @ 30uf. Correct?

Now if one takes another string just like the one above, and connects both strings across the output of the rectifier parallel to each other does this still give the 2500v but @ 60uf? or does the voltage drop?

Thanks

Gordon

2832. Need part for Tektronix 491 Spectrum Analyzer

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-11 01:38:30 UTC
From: Dave Woolf <NOSPAMdwoolf@worldnet.att.net>
Message-ID: <4078A1A9.1050001@worldnet.att.net>
Source record: 27069
Cross-posted to: sci.electronics.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.boatanchors

I am looking for a part for a Tektronix
491 spectrum analyzer. It is called the
RFI filter or the Low Pass 275 V AC Filter
The Tek part number as listed in my
service manual is 119-0095-00. It is a
metal can that on one end has the male
connector that the AC cord plugs into.
The other end feeds out the line voltage
to the internal fuses.

The failure is interesting. At some AC
voltage around 105 - 110 volts there is
a breakdown and short that blows a 20 amp
circuit breaker. The short is not permanent
as I can turn the unit off/on and it will again
work below the above voltage. I know it is
the filter as this is the only thing that is
before the internal fuse which never blows.

I have a work-around by running the unit
on a variac and keeping the voltage at
around 100 volts. But I am not sure how
long this will work, so I would like to
replace the filter.

Anyone know of a source?

Please remove NOSPAM from my e-mail address
if replying directly to me.

Thanks,
Dave Woolf - K8RSP

You are basically correct in your assumptions Gordon.

One thing to think about though is the balancing of voltages and currents across the string of capacitors. This is done by putting a high value resistor in parallel with each one of the capacitors.

The method can be seen in some of the plans for high boltage power supplies in the ARRL handbooks. If the voltages are not equally divided among the capacitors, one will get too much voltage and it will arc over internally.

This will effectively destroy that capacitor and then the rest of them will go bad in rapid succesion.

Under ideal conditions (perfect capacitors with no leakage resistance, etc.) the effective capacitance would be 30 uf and the voltage capability would be 2500 volts. If the original capacitors were pre charged to 500 volts, the series connected capacitors would produce 2500 volts. As a practical matter 5 capacitors connected in series would require ballast resistors to equalize the leakage current, and some voltage derating to allow for incomplete equalization.

Capacitors in parallel retain their voltage rating, and their capacitances add.

Gordon,

That is correct with a 'but' thrown in. If the capacitor values are
different voltage will be unevenly distributed. With the typical + or
- 20% tolerance using the string at 2500 volts is living on the edge.

It might work. If it doesn't you will find out in a few minutes. You
don't want to have your face in the circuit when it fails.

Well, with some care, you could make one. It's a lp filter that cuts off somewhere above 60 Hz. If you don't want to build one, try to find some discarded hospital electrical equipment. They all have filters that are tested for low leakage to the chassis.

Others have correctly answered your question. I'll
add something: one should always derate the voltage
that a capacitor "sees" in a circuit from the cap's
rating. Using a 500 volt cap at 500 volts is asking
for trouble. (Or using 5 of them in series at 2500
volts.) If your circuit runs at 2500 volts, add at
least one cap to the string.

And do not forget the bleeder/equalizing resistors.
You'll need 2 resistors in series per cap. I'd use
2 51K 2 watt resistors in series across each cap, to
give a very good safety margin on the resistors' power
dissipation and voltage exposure. Others might recommend
a single 100K 2 watt resistor across each cap. But that
way, each resistor "sees" about 416 volts, and dissipates
a little over 1.7 watts. With two in series, each resistor
"sees" about half the voltage - and the power dissipation
capability is doubled.

An active inverter is S L O W by comparison; a good, fast diode can
have turnoff times in the tens of picoseconds region.

Don't let Paul dream too much about picoseconds.
In order to achieve results that good, one have to pay very careful
attention to "wiring". There's still a lot of room for Paul to improve his
PCB design skills ;-)

Thanks,
Fred.

It's tragic, really. With very few exceptions, the actual mechanical
engineering on British cars is typically of a very high standard. The
overall product, however, is let down by Lucas electrics (where used)
and not terribly good rust-prevention treatment (which is
unforgiveable in a climate like ours).

Parametric operation is when you have a parameter such as diode capacitance that varies with voltage. The non-linearity of the parameter makes it act as a multiplier, mixer or an amplifier. Parametric amplifiers (they need to be 'pumped' with an oscilllator) used to be very popular for microwave use. If you have inadvertently make yourself a parametric amplifier with your diode it could oscillate given the right conditions and do all sorts of strange things. In your hands, this is a strong possibility. 8-)

I think you have a point Leon. Paul, use a Schottky diode, (HP 5082-2835 or similar), use ZERO lead lengths. Make your PCBoard for the multiplier double sided, drill a hole the diameter of the diode length, wrap a copper tape ground from top to bottom on one edge of the hole, and drop the diode in the hole and solder both ends. One end to the ground tape, the other to the land to the filter for the harmonic you want. Then, drive with not more than +10 dBm of fundamental and hope a lot. It may STILL oscillate, but you've maximized your chances. When you start getting output from the filter (on the desired frequency which ought to be the only output you can get with the filter in place) you can start matching the input to the diode with "L" networks to maximize the output. Generally, the diode looks like a quite low impedance so the capacitor used, ought to wind up on the side of the inductor AWAY from the diode.

You can use an MMIC in the same manner to generate harmonics. Overdrive it and under feed it with DC. More output, more chance of self oscillation if you don't pay attention to detail.

A superior (less touchy) method of harmonic generation is just a full wave diode rectifier. Using signal diodes and a center tapped transformer, make a full wave doubler. Ground the DC out with an RF choke and you have 2F the input frequency with good suppression of the fundamental and odd harmonics built in. It's then a lot easier to filter the rest of the undesired out. Do two of those to get 4F out rather than trying to do it all in one stage. LOTS more efficiency.

JC Whitney sells 12 volt panels competitively. These are not as
efficient when loaded to 6-9 volts, but they put out at least as much
current as when run with a 12 volt load.

I need 2 MAX232 level converters (DIP package).

Would like to swap for them. Have 2 MAX489CPD's
(RS485 transceivers) et al.
What do you need if these are not usable?
(active or passive parts, etc.)

Also need 2 4-pin 1/8" (3.5 mm) plugs.

Thanks for any offer,

Phil - N4GWV

Hi all

I have it back up without the balun, and still have to use the coax for now.
I am able to tune it now on all bands but I am sure there is a lot of power
loss from the tuner. I grounded out all devices in the shack but still
receiving a lot of RF interference on tv, computer, and home alarm.
Thanks for all the advice, really appreciate it.

Another option might be to use a different voltage panel,
whatever has a good price, and then use a small switcher to run
the cells at their optimum load.

Regards, Joerg.

2859. GS35B bias

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-12 01:25:52 UTC
From: Ron <ron_73@nomail.com>
Message-ID: <4079f007@news.iconz.co.nz>
Source record: 27096

Hi All,

I am working on an HF Amp project. This is my first tube (valve) project and it is all most finished and to my delight has great output. The question I have is about bias. I am using a 2N3055 transistor controlled by a 20 volt 1 watt zener with a rotary switch with s string of 3.3 volt 1 watt zeners that can be switched in or out to adjust the bias. This works great as I can adjust the key down no drive idle current from any where from 60 to 140ma. Now the problem is that in standby mode there is still about 20 at 30ma of plate current because of the so called "cut off" resistor (50K @ 10W) is still letting B- flow to the bias circuit. So can I simply eliminate this cut off resistor? Or would that cause the tube to open up and draw a massive amount of current? Or should I try to increase the value of the cutoff resistor?

Sorry if this is a simple question, But I just don't have much experience with power tube.

Thanks for your help
Ron

You've asked for a module that puts out 6-9 volts @ 100 mA. A more accurate description of a solar panel would be that it puts out 100 mA at 6-9 volts. Solar cells act a lot more like a current source than a voltage source. So a panel that's rated at 100 mA at 12 volts will also put out about 100 mA at 6 or 9 volts. (It'll be a bit more than 100 mA, but not a whole lot more.) The open circuit voltage of a "12 volt" solar panel (one intended to deliver current to a 12-14 volt load) will be somewhere around 18 or 20 volts, and one specifically designed to work at 6 volts will be about half that, 9 or 10 volts. So if you have a 6 - 9 volt device that you want to power with solar cells, you'll have to float the panel across a battery, or use a voltage regulator to limit the voltage. (A properly sized zener diode would be adequate for the power level you're dealing with.) A 12 volt panel will be physically larger than you need, but it might be easier to find and less expensive.

If you're looking for a module that includes a built in voltage regulator to limit the voltage to 6 - 9 volts, you need to make it clear. Most of the responses seem to be referring to 12 volt panels, which will be fine if you limit the voltage, but won't be suitable if you need voltage regulation to be included in the external module.

Roy Lewallen, W7EL

> rectifier do you need a centertapped transformer with roughly 160V in each
> winding, what they call a 160-0-160??

No! That will get you far less than what you need.

With theoretically "perfect" rectifiers and transformers, the output
voltage depends entirely on the type of filter and the transformer
voltage. With a full-wave center-tap rectifier and a choke-input
filter, the maximum voltage obtainable is 0.9 times the transformer
voltage, and with a capacitor input filter, the maximum voltage
obtainable is 1.414 times the transformer voltage. With the full-wave
center-tap rectifier, "transformer voltage" means "each side of center
tap".

The above numbers assume perfect components whose ratings are big
enough to do the job.

With real world components, it's a little more complicated, but the
results are always that you get less voltage.

The AC-1 uses a capacitor-input filter and a 6X5GT rectifier. Also,
the transformer is not "perfect" - just good enough to do the job. End
result is that the transformer is about 320-0-320 and the resulting DC
is about 325 volts.

Easiest way to work with tube rectifiers is to look them up in the
tube manuals (there are several tube manuals on-line) and look at the
design curves.
>
> I did see these other AC-1 sites and yes I do use the smaller resistor
> parallel to the crystal.

Excellent. May take some experimentation.

btw, check out AF4K's website for crystal suppliers.

Yes, but it's not necessary. You know the capacitors are the right
ones, so it's merely a matter of the chokes and coil.

> If I terminate it with a 50 load and feed my HF generator signal on the

That's exactly right.
>
> And what do you want the pi section to do, resonate at the transmitter
> frequency?

Yes. But more than just resonate, it transforms the load impedance
from 50 ohms to whatever the tube needs.

If I understand correctly, you're interested in harmonics up in the 70MHz region. To me it seems silly to use diodes capable of generating a comb of harmonics out to 20GHz for that. An advantage--a big advantage--of the tiny logic is that you get considerable power gain in the stage, and the sot-23 package is likely no larger than the diode you might have used anyway. The edges, as others have pointed out, are PLENTY fast enough for what I believe you want to do.

Whether you use diodes or gates, your size problem will be the harmonic-selection filter. As you've learned (and I trust not forgotten already), you need either multiple poles in your filter or a rather high Q. You _could_ get the high Q with crystals, but of course then you're locked down to particular frequencies. For high multiplication factors to low-VHF frequencies, it's probably hard to beat a PLL for (potentially) small size.

In offering suggestions, it would also be helpful to us to know your actual needs for signal purity, both close-in (phase noise) and broadband (other harmonics, etc.)

If you do use diodes for higher-order harmonic generation, and not just a simple full-wave-rectifier type frequency doubler, I suppose you want something of the nature of a step recovery diode. That implies minority carrier stored charge in the diode, and that would preclude using a Schottky diode (which would work great in the full-wave-rectifier type doubler). If you get into actually wanting to generate harmonic combs out to microwave frequencies, it's probably worthwhile looking for diodes actually characterized for step recovery service. But I really think that's way beyond what you are trying to accomplish right now.

Cheers,
Tom

You can replace it with a stock Corcom EMI filter from Digi-Key.

This thing is a pi filter with an inductor inside and some shunt
capacitors. One of the capacitors is on the way out.

My turn to learn something here. Tom, would you elaborate a bit on the above please? I know SRD's are comb generators out to visible light, but they're also 50 percent hard to find and 50 percent magic. I've been using Schottky's for X16 multipliers to 2 GHz, am I doing something wrong? (I keep promising myself that I'm gonna substitute an MMIC for that one day, I DID find the "Filter Gain" in the line length from generator to filter), THAT was both impressive AND helpful. If I go with the MMIC, any preference of Silicon over GaAs?

Regards

W4ZCB

The only distributor-stock SRDs I know of are the M/Acom MA44767,
MA44768, MA44769 parts, all SOT-23 and dirt cheap. I think Penstock
carries them. The '68 or '69 should be good for multiplication to 2
GHz. For high ratios, an SRD will beat a plain diode by a huge amount.
There are lots of appnotes around about using them as multipliers.

I have a bunch in stock and can send a few to anybody who wants to
play.

my pcb has a Linear Tech LT1117-5 LDO regulator on board, regulates 5volts with a min input Voltage of 6 volts, so I'm currently using 4 AA batteries in a battery pack with a 9v type clip. Wanted to be able to charge the batteries with solar cells basically.

But after searching the web a bit it seems cheapest to buy individual cells then tie them in series...No?

Seems foolhardy to me, to use a boost circuit, and waste a lot of power.
Just put more PV cells in series to increase the voltage.

Also the currewnt outputdepends somewhat on the latitude you're at. You
won't get all that current at the arctic circle.

He might actually have a better chance there during the periods when the sun never sets than at, e.g., the equator... solar cells are noticably more efficient when they're keep cold, which is typically a lot earier to do in the arctic than at the equator!

2874. Homebrew crystals for transmitters

Ahem, Joel, consider the location of "the land of the midnight sun..."

:-)

Ackshully, based on a little bit of experience on Solar One, the
first (of two) experimental 50 MWe solar plant in Barstow, CA,
(in the middle desert of California with not much else), sunlight
has a considerable variance in energy over the course of a day.
A combined buck-boost switching power supply would be a
consideration for reliable solar cell charging of a secondary
battery during daylight. There are several different ICs just for
the purpose of wide-voltage-range inputs from National, Linear,
and Maxim along with application notes from all three.

Roy Lewallen hit the subject nail on the head in saying, correctly,
that solar cells behave more as constant-current sources than
constant-voltage (as batteries are) sources. Those who care to
test that will find out from connecting a fixed resistor to solar cell
outputs and measuring the voltage during the course of daylight,
especially the differences between clear and cloudy skies.

Solar One was a boiler system, over 500 independent mirrors were
used as a giant reflector array to focus sunlight on a central boiler
made from the same stainless-steel-like tubing used in rocket engine
bell structures. Rocketdyne Division of Rockwell International was
the subcontractor to MacDonnell-Douglas that made the boiler and
the underground steam-heat storage system of Solar One. The peak
daylight energy was in excess of 100 MWe equivalent but the extra
heat had to be stored overnight for the steam-turbine-powered
generators to run 24/7. Rocketdyne, now purchased by Boeing,
made the Space Shuttle Main Engines. Rocket engine bells
are made from tubing to circulate fuel before entering combustion.
That pre-warms the fuel as well as cooling down the tail of the
engine's output.

Not exactly what a QRP operator would need... :-)

For 6V, I would put two of these in series, along with a 1N5817 schottky
diode to prevent reverse current. Each cell is encapsulated with epoxy
and the wires can be soldered to the pads on the back. Each puts out an
honest 30 mA, or more in bright sunlight. Price is reasonable too.

http://www.allelectronics.com/cgi-bin/category.cgi?category=565&item=SPL-60&type=store

You can also put two pairs in parallel to get a faster charge.

That's why I said 'during the periods when the sun never sets' -- it's about half the year with no light, and half with no darkness, no? :-)

After all, during the 'no light' periods he doesn't have to run the air condtioner anyway, right? Just kidding!

My experience with tying together solar cells is that you'll probably
destroy a few along the way (the pads lift very easily when heated
with soldering iron), so either get extras or go with a solution which
does not require you to solder cells together (or be more careful than
I was, I guess).

Thanks! Those are good resistors - I didn't know
about the site. My paranoia extends to the caps, too.
I would use 7, myself, yielding a total of 3500 volts
or about 360 across each cap and resistor. That would
also reduce the power the resistors would dissipate to
about 1.3 watts, but the reduction in cap voltage
is more important. The last one I built (for 1800V)
used 6 450 volt caps and 12 51K 2w resistors. Wish
I had known about that site when I built it - I would
have used those resistors.

2883. Help Finding Latching Relay

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-13 03:32:04 UTC
From: randy
Message-ID: <konm70h13pqe0jhg14o2rtpke86qioqcc2@4ax.com>
Source record: 26970

I'm looking for a source of new latching relays.

Coil needs to be 12 to 24 volt and contacts of 10 amps at 120 volts AC.

The catch is I don't want any dual coil type relays. I have an application in which I want a contact closure on the coil to turn the relay on and another closure will turn it off again.

I would even be receptive to a solid-state module that would give me the pulse on / pluse off action that I could use to control a relay.
